Applicational Grammar

J Miller, University of Auckland, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

In linguistics, as in all other areas of intellectual activity, ideas catch on not just because they are good but also because they arrive at the right time and in the right place. Developed at the wrong time and in the wrong place, Applicational Grammar (AG) is nonetheless a remarkable, if ultimately unsuccessful, achievement.

Background

Applicational Grammar (AG) was developed between the early 1960s and the mid-1970s by Sebastian Konstaninovich Shaumjan of the Institute of Russian Language at the Soviet Academy of Sciences. The first versions of the model were phonological; a detailed account of the model applied to syntax was published in Shaumjan (1965).

In 1965, Chomskyan transformational generative grammar was becoming the major formal model in North America and was beginning to spread to the UK and other countries. Montague's categorial grammar would not be published until 1970 (Montague, 1970a,b). Shaumjan's work from the early 1960s was not well received by North American generativists, and the translation of his 1965 book (Shaumjan, 1971) went unnoticed in the excitement over Montague Grammar. Nonetheless, Shaumjan's theory is no less rigorous than Montague's; he draws on a wider range of logical and linguistic theory, and his model is informed by knowledge of a number of languages in addition to English. His treatment of certain constructions is interesting; for example, Shaumjan (1965) proposes an analysis of complement clauses that anticipates Thomason (1976).

Shaumjan (1977) extends AG to handle semantic structures and the mapping of semantic structures onto syntactic structures. This later version of the grammar is influenced by generative semantics and the work of Fillmore on lexical decomposition, and also by Kilby (1977). Shaumjan (1977) was really innovative, however, in attempting to combine categorial grammar and what is now known as Situation Semantics.

The focus here is on Shaumjan (1965, 1971), because that model exhibits most clearly the properties distinguishing it from other generative models.

The Properties of Applicational Grammar

The Basic Units

The basic units are *term* and *sentence*, as is usual in categorial grammar. *Term* is represented by α, *sentence* by β. Other units, derived by combining the two basic ones, are interpreted thus: e.g., $\alpha\beta$ – a unit

or category applying to a term (α) to yield a sentence (β), i.e., a verb; $\alpha\alpha$ – a category applying to a term to yield a term, e.g., an adjective; $\alpha\beta.\alpha\beta$ – a category applying to a verb to yield a verb, e.g., an adverb; $\alpha\alpha.\alpha\alpha$ – a category applying to an adjective to yield an adjective, e.g., an adverb such as *very*.

Shaumjan extends the categorial treatment to the structure of words, adopting Kuryłowicz's view that syntactic and morphological relations are parallel – e.g., that a change in syntactic function from predicate to attribute is paralleled by the change from finite verb to participle: *The child slept* vs. *the sleeping child* (examples are Russian and English).

He also accepts Kuryłowicz's view that different word classes have different primary and secondary functions. For adjectives, the modifying function is primary: they map terms into terms, and include more than the traditional adjectives. For instance, they include derivational affixes deriving nouns from nouns (or terms from terms) – *hood* in *childhood*, and the diminutive suffix *-ik* in Russian *domik* ('little house') – and nouns in the genitive case or with the English possessive affix. *Fiona's* added to *house* yields the term *Fiona's house*. In Russian, a noun in the genitive case – e.g., *studenta* ('of the student') – combines with a noun in the nominative case – e.g., *kniga studenta* ('the book-of the student') – to yield a term. This is a secondary function of the noun *student*, which is signaled by the genitive case. The primary function of nouns is to be a basic term to which verbs apply to yield sentences. This function is signaled by the Russian nominative case.

Other items belonging to the category adjective are prepositional phrases – *about gardening* combines with the term *books* to yield the term *books about gardening* – and participles, such as English *sleeping* from *sleep* and Russian *igrajushchij* ('playing') from the stem *igra-*. The primary function of verbs is to apply to a noun to yield a sentence. One secondary function is to act as an adjective, which is signaled by the participial suffix.

Derivations

Combinations of items are generated by a single operation called 'application' – whence the title 'applicational grammar.' Application, from Curry's work – cf. Curry (1963), involves an operator applied to an operand. The notation – typical categorial notation – indicates, for a given case, the operator, the operand and the result of the application. Thus, for the item $\alpha\beta$, β labels the category of the operator, α labels the category of the operand and $\alpha\beta$ labels the category into which the operand is mapped. Suffice it to say here that the derivational system is rigorously defined, with a set of primitives and a rule for deriving new items from the primitives or from other derived items.

Different Levels of Category

To treat *Fiona*'s, etc., merely as instances of a general category $\alpha\alpha$ would be to ignore differences between them: *igrajushchij* derives from a verb, *studenta* is a noun in the genitive and *about gardening* is a prepositional phrase. Moreover, *-ik* in *domik* and -α in *studenta* are part of the internal structure of words. Another problem, as mentioned in 'The Basic Units,' is that while being an adjective is the primary function for, e.g., *small*, it is a secondary function for the participle *igrajushchij*.

AG solves these difficulties by having a top level of 'episemions,' the general categories presented in 'The Basic Units,' and a lower level of 'semions,' which are narrower categories in that a given semion has a structure showing its derivation. Shaumjan captures that structure by means of a 'relator notation' and language (one possible actual 'calculus' of semions.)

Relators: Derivational Morphology and Syntactic Function

There are five relators, R_1 to R_5. R_1 represents the category $\alpha\beta$, R_2 – α, R_3 – $\alpha\alpha$, R_4 – $\alpha\beta.\alpha\beta$, and R_5 – $\alpha\alpha.\alpha\alpha$. They apply to an empty root 0, or to any combination of relators and 0, or to an entire phrase, i.e., to some sequence of R_n0s. If 0 is the root *uch-*, R_1 applies to yield $R_1$0, corresponding to finite forms of the verb: *uchit* ('teaches'), *uchim* ('we teach'), etc. In turn, R_2 applies to $R_1$0 to yield $R_2R_1$0, corresponding to nouns derived from the verbal stem, such as *uchenie* ('teaching') and *uchitel'* ('teacher').

The sequences of relators correspond to stages in the derivational morphology of a given word. If 0 is *zim-*, R_2 applies to yield $R_2$0 – *zima* ('winter'). R_1 applies, yielding $R_1R_2$0, corresponding to a finite verb form – say, *zimuem* ('we pass the winter (somewhere)'). R_2 applies to yield $R_2R_1R_2$0, corresponding to *zimovka* ('the act of wintering'), and the formula corresponding to *zimovochnyj* ('winter' as in 'winter quarters') is derived by applying R_3 to yield $R_3R_2R_1R_2$0.

Unlike the last Russian example, *winter* can be noun, verb or adjective without derivational affixes. Nonetheless, the adjective *winter* in *winter quarters* would correspond to the formula $R_3R_2R_1R_2$0, R_3 signaling its modifying function.

Russian has various cases. Only nouns in the nominative case correspond to R_2, because only they combine with a verb to form a sentence. Nouns in the genitive case correspond to R_3, because they have

an adjective function: they map terms onto terms. Nouns in other cases correspond to R_4, because they map verbs onto verbs: the accusative case form *kartu* ('map') combines with *chitaet* ('reads') to yield *chitaet kartu*, which combines with the nominative noun *soldat* ('soldier') to yield the sentence *Soldat chitaet kartu* ('The soldier reads the map'). English has no case, but nouns do have different syntactic functions and correspond to different formulae: in *The soldier is reading the map, the map* is R_4 because it maps the verb *is reading* into the verb *is reading the map*, and the *soldier* corresponds to R_2 because it combines with that verb to yield a sentence.

Other Primitives in the Relator Calculus

In addition to relators and 0, the relator calculus has 'adnectors,' 'connectors,' and 'propositors.' Adnectors are identity elements interpretable as, e.g., negation and interrogation, which apply to a given linguistic element leaving it identical with itself. Connectors correspond to conjunctions such as *i* ('and'). Propositors convert phrases and clauses into the *determiners* of clauses. Thus, *if* converts the clause *it is raining* into a subordinate clause acting as determiner to another clause: *If it is raining, I am going to stay at home*. The phrase *according to the instructions* can function as an R_4 in, e.g., *We prepared the vegetables according to the instructions*; it can function as a determiner of a clause, as in *According to the instructions, you were to wait there till help arrived*. Subordinating conjunctions such as *if* always function as propositors, whereas phrases such as *according to the instructions* may or may not function as a propositor.

Sentences and Transformational Fields

0 with one or more relators corresponds to a word in English or Russian. In turn, an element R_n0 can apply to another R_n0 to create a more complex element. R_30 applied to R_20 generates R_30R_20, which can be interpreted as *splendid parties*. As it stands, R_30R_20 cannot be interpreted as having any particular syntactic function, but the relator R_4 can be applied to generate $\|R_4|\ R_30R_20$, i.e., an $\alpha\beta.\alpha\beta$ mapping a verb onto a verb. $\|R_4|\ R_30R_20$ applies to an R_1 item, say R_10 to generate $\|R_4|\ R_30R_20R_10$, interpretable as *gives splendid parties*. The above sequence, an instance of $\alpha\beta$, maps a term into a sentence, applying, say, to R_20, to generate $\|R_4|\ R_30R_20R_10R_20$ – *Gatsby gives splendid parties*.

AG can generate, quite independently of each other, the 'analogs' of *Gatsby ruined that party* and *That party was ruined by Gatsby*. In the relator analog of the active sentence *Gatsby* corresponds to R_20, a term looking for a verb to map it into a sentence. In the analogue of the passive sentence, *Gatsby* corresponds to R_4R_20, an item mapping a verb into a verb. These remarks apply, vice versa, to *that party*.

Transformational Fields

Generative grammar expresses relationships between different constructions, but the independent analogs of active and passive sentences do not. To overcome this defect, AG generates the analogs of sets of sentences by means of graphs.

Down the left-hand side of a given graph are the relators, ordered from top to bottom in the sequence R_5, R_3, R_2, R_1, R_4. This order reflects possible applications: an R_5 item applies to an R_3 item, an R_4 item to an R_1 item, and so on. Across the top of the graph is the expression to be transformed, the 'base,' which can be the analog of a sentence or the analog of a phrase. Each relator is applied to each R_n0 in the expression across the top of the graph and the result is written in the column below the R_n0.

The set of R_n0s generated constitutes a 'transformational field,' represented by a graph with the R_n0s arranged in columns and rows. Two restrictions can be placed on the generative process: (a) the graph is connected; and (b) head-modifier links between items in the base expression are preserved in the derived expressions. If (a) and (b) are both imposed, the transformational field is *bound*; if (a) alone is imposed, the field is *semibound*; if neither is imposed, the field is *free*. (NB: Head-modifier links relate to phrases only: the subject–predicate link is not one of head and modifier.)

For example, if the base is $R_30\ R_20$ – *striking beauty*, one transform is $R_5R_30\ R_3R_20$ – *strikingly beautiful*, which maintains the head-modifier links. Suppose that the base is $R_20\ R_10\ R_4R_20$ – *The train arrived from Moscow*. One transform is $R_3R_4R_20\ R_2R_20\ R_1R_10$ – *The Moscow train arrived. From Moscow* is a modifier of the verb in the base expression, but a modifier of the subject noun in the transform: i.e., the head-modifier links are altered.

The base can be a more complex expression, say $\|R_2|\ R_30R_20$ (*imaginative students*) R_10 (*write*) $\|R_4|\ R_30\ R_20$ (*interesting essays*). The initial R_2 applies to the adjective–noun block, and the R_4 applies to the final adjective–noun block. The graph generates, inter alia, $R_4\|R_2|\ R_30\ R_20\ R_1R_10\ R_2\|R_4|\ R_30\ R_20$, which is the analog of *Interesting essays are written by imaginative students*.

Genotype and Phenotype Grammars

The model described above is a 'genotype' grammar; i.e., a grammar handling the generic properties of

language. The sequences of semions are mapped onto sequences of, e.g., Russian, English, or Georgian morphs by 'phenotype' grammars which assign word order, morphological categories and phonological shape.

The Later Model

Shaumjan (1977) extends the model to semantics. The derivational apparatus is essentially the same, but the relator genotype language represents the analog of semantic structures: the relators correspond to the relations of 'predicate logic,' with the restriction that they are all 'two-place' in the axioms. The axioms belong to the category β, i.e., are sentences, and correspond to components of situation models.

The situation models are 'localist,' that is, based on the assumption that the semantic representation of any situation has as its central components a predicate of location or movement, the case relations of location, movement from or movement to, and the case relation 'objective,' which corresponds to the entity conceived of as being located somewhere or moving somewhere. For instance, *Fiona gave Bill his essay* is derived from a semantic structure which has an event coming from Fiona – represented by a 'two-place predicate' – and the event is the essay coming-to-be-located at Bill, which event is also represented by a two-place predicate.

The axioms state the possible relationships between entities: $R_{oa}T^1T^2$ represents a 'two-place relator,' and the two terms correspond to two entities, one of which moves away from the other. The subscript letters on R represent the case relations and at one stage in the derivation are copied onto the terms. The order is important, since it indicates that the *theme* is ablative and the *rheme* objective: that is, the entity from which the other entity moves away corresponds to the surface subject, and the other entity is in the rheme of the surface sentence. For example, R might correspond to *sent*, T^1_a to *Bill*, T^2_o to *telegram*, and the whole axiom to *Bill sent a telegram*. In contrast, $R_{ao}T^1T^2$ corresponds to *A telegram was sent by Bill*.

Rules of derivation generate surface sentences from the sequence of semions representing the semantic structure. One semion, **B**, triggers the fusion of semions: e.g., the mapping of *cause-be-located* into the single lexical item GIVE. Another semion, labeled C, causes terms to be permuted, as in the derivation of the relator expression corresponding to *They loaded the barges with timber* from the relator expression corresponding to *They loaded timber on the barges*. The reordering rules with C, like the matrix graphs in the 1965 model, express relations among different constructions.

As in the 1965 AG, once relators and terms have been fused and ordered, a phenotype grammar maps the expressions onto sentences of a given language. The phenotype mappings are organized around particular groups of lexical items. For instance, the general lexeme GIVE_{ola} is a cover term for verbs with a particular valency, such that the theme term corresponds to the giver, the second term (here the direct object) – to the person at whom something comes to be located, and the third term – to the entity that moves, i.e., GIVE_{ola} is a cover term for Z EQUIP X WITH Y, Z PROVIDE X WITH Y, Z PRESENT X WITH Y, Z REWARD X WITH Y, and so on. Each group of lexical items has its own order of nouns, its own prepositions and, for Russian, its own case endings. The valency is crucial: an item with two valencies – Z PRESENT X WITH Y and Z PRESENT Y TO X – is treated in the phenotype grammar as two different items, although the two valencies correspond to one item in the genotype grammar. The corresponding basic relator in the genotype grammar is R_{loa} (Z PRESENT Y TO X), but the order of terms is changed by a derivational rule with C. Even passives and constructions with reflexive verbs (in Russian) are derived by rules with C.

A Critique of Applicational Grammar

Like the classical transformational model, the 1965 AG model focuses on syntax while the 1977 model, possibly reflecting generative semantics of the late 1960s, maps semantic expressions onto surface sequences where morphological categories are much in evidence but syntax is absent.

The 1965 model was to contribute to grammatical synonymy and to typology. Given a base expression and the expressions derived from it, two properties could be measured: within a single language, the degree of synonymy between any two of the derived expressions could be measured by the number of subexpressions they shared; with respect to typology, any two languages could be compared according to which derived formulas are interpretable in both languages and which only in one.

Although AG is remarkable for its rigor and formal consistency, the claim concerning typology highlights a fundamental weakness. The elementary semions are based on certain characteristics of natural languages, but the derivational procedure was devised by Curry to generate completely abstract uninterpreted objects capable of being put in correspondence with any appropriate entities, linguistic or mathematical or whatever. The derivational procedure is defined with great rigor, but, apart from the

basic combinatory possibilities, is so remote from natural language that the advantages of the model are outweighed by its limited scope. Offering little for dependency relations and nothing for constituent structure, AG is irrelevant to language acquisition and to typological studies of dependency relations, the order of heads and modifiers, the question of flat vs. hierarchical constituent structure, and the question of clause-embedding vs. clause-chaining.

AG reflects a fundamental tension in formal linguistics: the difficulty of developing a formally rigorous model that expresses interesting and exploitable hypotheses about linguistic structure. Formal rigor comes with systems borrowed from metamathematics, and Shaumjan adopts the notion of a metalanguage formulated so precisely that its reasonings could be seen as derivations according to precise rules, whose correctness of application can be seen by inspecting the symbols of the metalanguage regardless of any meaning they might have. The trouble is that, outside mathematics, the axioms of a given system must have a degree of truth or falsity with respect to a given subject-matter, and a degree of interest. Shaumjan's axioms are true insofar as his categories are not without linguistic support. There is formal rigor in plenty, but in linguistic theory and its major applications the axioms have hitherto failed to arouse excitement.

Shaumjan left the Soviet Union in the late seventies. Political problems led to the disbanding of the then Institute of Russian Language, and Shaumjan's model disappeared (undeservedly) from the map of linguistic theory.

Applied Forensic Linguistics

J Gibbons, Hong Kong Baptist University, Kowloon Tong, Hong Kong

© 2006 Elsevier Ltd. All rights reserved.

Forensic Lingustics attempts to describe, and where possible explain, those features that distinguish the language used in legal settings from everyday language. *Applied Forensic Linguistics* addresses issues and problems in the legal system that are language based. Some of these applied forensic linguistic problems and issues arise from the nature of the language used in the legal system. The written technical language of the law is extraordinarily complex and can be virtually impossible for nonlegal specialists to understand (*see* **Language of Legal Texts; Legal Genres**). The social issue is that there is a contradiction between (a) the fact that most people cannot be expected to understand the language of the law, and (b) the legally enforced principle that ignorance of the law is no defense. The first contribution of applied forensic linguistics is to demonstrate that ordinary people cannot understand legal language. The majority of the work in this area has been done by psycholinguists (see in particular Felker *et al.*, 1981). Some notable work has also been done by sociolinguists (Labov and Harris, 1994). Solutions to these problems have been sought mainly by the Plain Legal Language movement, including document design specialists.

Spoken legal language can similarly be a social issue. Court proceedings have often been described

basic combinatory possibilities, is so remote from natural language that the advantages of the model are outweighed by its limited scope. Forensic Lingustics attempts to describe, and where possible explain, those features that distinguish the language used in legal settings from everyday language. *Applied Forensic Linguistics* addresses issues and problems in the legal system that are language based. Some of these applied forensic linguistic problems and issues arise from the nature of the language used in the legal system. The written technical language of the law is extraordinarily complex and can be virtually impossible for nonlegal specialists to understand (*see* **Language of Legal Texts; Legal Genres**). The social issue is that there is a contradiction between (a) the fact that most people cannot be expected to understand the language of the law, and (b) the legally enforced principle that ignorance of the law is no defense. The first contribution of applied forensic linguistics is to demonstrate that ordinary people cannot understand legal language. The majority of the work in this area has been done by psycholinguists (see in particular Felker *et al.*, 1981). Some notable work has also been done by sociolinguists (Labov and Harris, 1994). Solutions to these problems have been sought mainly by the Plain Legal Language movement, including document design specialists.

Spoken legal language can similarly be a social issue. Court proceedings have often been described

as a battle between two competing accounts of the issue under litigation. Heffer mentions that aggressive competition between counsel may negatively affect a jury's ability to adequately assess the evidence and reach a decision, an applied linguistics challenge. One consequence of competing versions is that during the legal process, a police officer or lawyer will often try to impose a particular version of events upon witnesses by using a range of linguistic devices. The following lawyer's question is an example.

> Lawyer: According to your writing the events last year, that during the break, you were handed some car magazines to read? Is that correct?

The first thing to note is that like much courtroom examination, this is not question, but a statement. It is harder to answer "no" to a statement than a question. Second, the statement is followed by a confirmation tag "is that correct?" Third, the core information, that the witness was handed some car magazines to read, is embedded as a form of projection or report of the witness's own writing? "According to your writing . . . " The accumulation of such linguistic devices puts considerable pressure on the witness to agree. There is now a substantial literature that confirms that witnesses on occasion agree to information that they know to be false and with which they disagree, as a consequence of this type of linguistic pressure. The social issue that emerges is whether this type of language is ethically justified. Furthermore, the question given above was directed to a 15-year-old testifying that she had been sexually assaulted at the age of 13. It is hard to justify this type of questioning of victim witnesses and vulnerable witnesses (*see* **Interviewing and Examining Vulnerable Witnesses**).

Apart from the issue of linguistic pressure on witnesses, there is evidence from many contexts that certain social groups are in danger of being disadvantaged as a consequence of the language used in the legal system, since they may not understand the language and culture of the law. There is extensive documentation of miscommunication with indigenous minorities (see Eades, 1994; Walsh, 1994; Stygall, 1994), the deaf (Brennan and Brown, 1997), children (Walker and Warren, 1995), and second language speakers (Jensen, 1995).

Various ways of addressing these problems have been proposed; most involve courtroom procedure. In the court where the question given above was asked, rules of procedure were in place that should have prevented the question from being used, but there are many cases where judges do not enforce such procedural rules. This points to another means of addressing the problem: lawyer training, both pre-service and in-service. Other aspects of courtroom and police procedure can involve the presence of a support person for the witness, the use of an intermediary between lawyer or police officer and witness, or the use of distance technology. There is also a strong argument for access to interpreters to assist in communication whenever there is a possibility that they can make a useful contribution.

A related area is police language, particularly the formulaic cautions or warnings given by police officers, which tend to be written in a legalese that is difficult to understand. The applied linguistic work done here involves working with police to clarify their wording (Gibbons, 2001).

Legal interpreting and translation also constitute applied forensic linguistic challenges. One major challenge is translating legal documents into a language that does not share a legal concept with the source language. The extreme complexity of legal language is in itself a translation challenge. Solutions include the education of legal professionals in such issues, specialized training for legal translators, and establishing bilingual legal language databases to facilitate the search for equivalents. Legal interpreting demands a high level of accuracy in real time. Such interpreting is also mainly consecutive, which places a further demand, that of memory. Research has found that in the courtroom context, interpreters tend to prioritize the interpreting of factual information and may poorly interpret interpersonal and discourse aspects (see also Hale and Gibbons, 1999). The quality of legal interpreting may also be threatened by inadequate resources. Solutions include actions to improve funding and appropriate training for interpreters and others working in the legal system with the challenges of legal interpreting.

Another applied forensic linguistic concern is law on language. An important case is that of national languages and minority language rights, which fall into the applied linguistic area of language planning and policy (*see* **Language Planning and Policy: Models**). Arriving at solutions that both respect rights and are practicable is a substantial challenge. Decisions concerning languages that may be used or interpreted in legal systems is even more central to forensic linguistics: permission to use one's mother tongue or strongest language in court is a social rights issue, but may be difficult to implement in practice. The paradigm case is where a witness speaks a language that has only a small number of speakers, and few or no fluent bilingual speakers capable of managing legal issues, including interpreting and translation.

Another law on language issue, particularly in Common Law, the right to silence is an issue (Kurzon, 1998). More applied linguistics research is needed on

where and why silence is chosen (it is not necessarily an admission of guilt: if charged with a serious offense many people would claim the right to silence until a lawyer is present) and on the consequences of this choice on legal communication.

Other areas in which the law regulates language are offensive language, slander and libel, and vilification. Linguistic analysis may reveal the language resources that are used to commit these offenses, and inform applied linguistic decisions on where banning is likely to be effective and in the interest of the individual and/or society. It may also enable linguists to present evidence in court as to whether one of these offenses has been committed. Shuy (1993) discusses the presentation of such evidence, and also the nature of a range of other language crimes such as threats, bribery, perjury, and broken promises.

The most widely discussed area of applied forensic linguistics is that of language evidence. This can be divided broadly into areas of identification and communication. One form of identification is speaker profiling, which often entails the use of phonetic data, and sometimes computer-based analysis of speech sounds (Hollien, 2001). Other forms of identification are the identification of writers, sometimes through vocabulary and grammatical patterns, which may also use computers. It may involve the comparison of two or more language samples, to see if they were produced by the same person. The detection of plagiarism similarly involves forensic linguistic analysis. In profiling, language behavior may give clues to a range of identificatory features, including sex, sexual preference, age, social class, geographic origin, and level of education. On other occasions, forensic linguists may be called upon to determine whether a particular person did or did not produce a particular piece of writing or speech. Once more, a whole range of linguistic levels may be involved such as phonetic evidence on individual pronunciation, social variation, and lexical, grammatical, and discourse evidence.

Evidence on communication includes the source and nature of misunderstanding, particularly among people of different linguistic or cultural backgrounds. There are many studies where linguists have shown that people cannot understand legal texts (Levi, 1994). There is also a substantial literature on miscommunication between lawyers or police and linguistic minorities (see, for instance, Gumperz, 1982). Evidence on communication may also include the decoding of various types of secret language, including pig latin and other codes (for examples, see Gibbons, 2003: 294–295). It also includes the question of trademarks because there is an issue of what trademarks communicate, as well as deciding how similar trade names are.

One problem area for linguistic evidence is that of reliability and admissibility. It can be very difficult for a linguist to provide an exact measure of the reliability of evidence; sometimes broad categories such as 'fairly likely' are used in linguists' judgments. Having the testimony of applied linguists accepted as evidence in court is a continuing problem, particularly in the United States.

The final area of applied forensic linguistics is that of the language training of legal professionals. In countries such as India, the legal system operates mainly in English, a second language for almost all Indians, and the same issue arises in much of Africa (whether the language be French, English, or Portuguese). Indeed, a substantial proportion of the world's legal systems operate in a language that is for local lawyers a second language or a distantly related dialect. Given the complexity of legal language mentioned above, teaching the language of the legal system to lawyers is an important and difficult matter. Solutions involve careful needs analysis of legal language and the development of tailored curricula.

Since the law is an overwhelmingly linguistic institution, language is implicated in many of the issues and problems associated with the legal system. Applied forensic linguists have made a substantial contribution to addressing these issues and problems, and as their work becomes more recognized, there is every likelihood that their contribution will expand.

Applied Linguistics in Africa

R Wildsmith-Cromarty and D Young, Universities of KwaZulu-Natal and Cape Town, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Within a framework of postmodern and postcolonial theory, much applied linguistic work in Africa today is in response (and resistance) to the erstwhile creations of the colonial period. There is an underlying tension between the legacy of colonialism in the form of the excolonial languages, which carry status and economic opportunity, and the need to protect and develop the indigenous African languages in the face of rapid globalization. For applied linguists working in these contexts, this translates into the need for effective, high-quality language teaching programs in the excolonial languages, from early literacy to professional contexts, while simultaneously contributing to the development of multilingualism through research into and development of the indigenous languages.

Language issues in Africa have been the focus of vigorous ideological debates, some of which are underscored by an increasingly Africanist perspective. What is missing in the Western-based discourses about African language development is an **African** perspective, drawn from the local communities themselves, and represented and researched by **African** applied linguists. For example, the construct of *indigenous languages* is perceived as an arbitrary division of a natural continuum. A term that reflects language use across boundaries, such as *communitarian languages*, is considered preferable (Makoni and Meinhof, 2003: 7). Further information on ideological debates in the African context can be found in Alexander (1989), Bamgbose (1991), and Blommaert (1999). However, what internationally is classified as applied linguistics is often hidden or euphemized under labels such as language education, African Languages and Literatures, Applied Language Studies, among others. For a fuller discussion of the recharacterization of applied linguistics, see Young (2001).

Multilingualism and the Role of the Excolonial Languages

Applied linguistic research and practice on the African continent has to deal with complex sociolinguistic profiles and ideologically and logistically complex language issues. Most African countries are multilingual in that the majority of the populations speak more than one language, and often three or more. However, in many of these multilingual societies, the official business of the country is carried out on a monolingual basis, usually through the medium of an excolonial language, such as French, English, or Portuguese. For example, in fifty-six African countries, twenty-two have French as an official language; seventeen, English; eleven, Arabic; five, Portuguese; and one, Spanish (Webb and Kembo, 2000). In Nigeria, there is also rivalry between English and French as official languages, as there was in South Africa between English and Afrikaans. Webb and Kembo (2000: 312) provide a bird's-eye view of the language profiles of the African states, including their population figures, number of languages spoken, main languages spoken, official languages, and literacy rates.

A number of African countries have proclaimed an African language as an official language, for

Within a framework of postmodern and postcolonial theory, much applied linguistic work in Africa today is in response (and resistance) to the erstwhile creations of the colonial period. There is an underlying tension between the legacy of colonialism in the form of the excolonial languages, which carry status and economic opportunity, and the need to protect and develop the indigenous African languages in the face of rapid globalization. For applied linguists working in these contexts, this translates into the need for effective, high-quality language teaching programs in the excolonial languages, from early literacy to professional contexts, while simultaneously contributing to the development of multilingualism through research into and development of the indigenous languages.

Language issues in Africa have been the focus of vigorous ideological debates, some of which are underscored by an increasingly Africanist perspective. What is missing in the Western-based discourses about African language development is an **African** perspective, drawn from the local communities themselves, and represented and researched by **African** applied linguists. For example, the construct of *indigenous languages* is perceived as an arbitrary division of a natural continuum. A term that reflects language use across boundaries, such as *communitarian languages*, is considered preferable (Makoni and Meinhof, 2003: 7). Further information on ideological debates in the African context can be found in Alexander (1989), Bamgbose (1991), and Blommaert (1999). However, what internationally is classified as applied linguistics is often hidden or euphemized under labels such as language education, African Languages and Literatures, Applied Language Studies, among others. For a fuller discussion of the recharacterization of applied linguistics, see Young (2001).

Multilingualism and the Role of the Excolonial Languages

Applied linguistic research and practice on the African continent has to deal with complex sociolinguistic profiles and ideologically and logistically complex language issues. Most African countries are multilingual in that the majority of the populations speak more than one language, and often three or more. However, in many of these multilingual societies, the official business of the country is carried out on a monolingual basis, usually through the medium of an excolonial language, such as French, English, or Portuguese. For example, in fifty-six African countries, twenty-two have French as an official language; seventeen, English; eleven, Arabic; five, Portuguese; and one, Spanish (Webb and Kembo, 2000). In Nigeria, there is also rivalry between English and French as official languages, as there was in South Africa between English and Afrikaans. Webb and Kembo (2000: 312) provide a bird's-eye view of the language profiles of the African states, including their population figures, number of languages spoken, main languages spoken, official languages, and literacy rates.

A number of African countries have proclaimed an African language as an official language, for

example: KiSwahili in Tanzania and Kenya; Amharic in Ethiopia; Sesotho in Lesotho, and Tigrinya in Eritrea. Some countries, such as Eritrea and South Africa, recognize more than one African language as official languages (Constitution of the Republic of South Africa, 1996). Although these policies may give greater recognition to **all** indigenous languages, the trends are toward convergence and language shift, often from the local languages to other major African languages, such as Sesotho for Tshivenda and Xitsonga speakers in South Africa, or toward Swahili in Kenya and Tanzania (Abdulaziz, 2000). The functions of these local African languages are still subsidiary, being used for instruction in lower primary school, adult literacy, local and regional administration, and in informal contexts (Bamgbose, 1991). In Mauritius, French-based Creole is the popular lingua franca, while French is the prestige lingua franca, and English is the language of education, business, and government. This situation engenders major language-of-instruction difficulties in schooling and tertiary education (Owodally, 2004).

The use of the excolonial languages, or a major African language, as languages of instruction and official communication, limits access to information for the majority of speakers of local languages. This situation serves to maintain an educated minority, and has serious consequences for literacy (Moyo, 2003). The response to this has been the establishment of various language development initiatives on the continent, some of which entail interstate collaboration. Applied linguistic research in Africa is thus moving from a preoccupation with the teaching of the excolonial languages, to advocacy work and development of the African languages to ensure equitable access to resources. Information on the roles of various languages and new urban varieties in African countries appears in Muthwii and Kioko (2003) and Mesthrie (2002).

Language Development: Some African Initiatives

A number of initiatives established in various African states aim to increase the status and functions of the indigenous African languages, with special emphasis on crossborder languages, to strengthen relationships between the peoples of Africa, and to promote literature and the oral tradition. In Nigeria, the Language Development Center promotes standard orthographies for local Nigerian languages, and the River Readers project has helped to increase their status (Abdulaziz, 2000). In Cameroon, a Language Committee has been established to research and support the status of local languages at the regional level (Tadadjeu, 2004). Two further initiatives are the establishment of the African Academy of Languages (ACALAN) by the President of the Republic of Mali (ACALAN, 2002: 17) in 2001, and the Pan South African Language Board (PanSALB, 2000) in 1995, to promote multilingualism in South Africa and to develop nine of the eleven official South African languages (SiSwati, isiNdebele, isiZulu, isiXhosa; Sepedi, Sesotho, Setswana, Xitsonga, and Tshivenda). Their work involves accelerating the introduction of African languages into the education system, the legal system, and in administration. They also have links with bodies such as the African Association of Lexicography (Afrilex), established in 1995 to promote research and teaching in lexicography and terminology, especially in the fields of science and technology.

An important area of concern are the problems experienced by learners and local communities in understanding and using newly coined terms which are experienced as artificial, or as belonging to a deep, often rural, variety of the language, which is unfamiliar to the more urban population (Anthonissen and Gough, 1998). An analysis of existing terminology is needed to evaluate its efficiency in the current educational context, coupled with a more participatory approach to language development. Such an approach is discussed with reference to corpus development of Chichewa in Malawi (Banda, 2001). The opinions of first language speakers influenced key decisions regarding the inclusion in the corpus of certain consonants that were applied variably by different native speakers. Banda (2001) provides further information on corpus development of African languages across borders.

Translation and Interpretation

A much-neglected area of applied linguistic work concerns the training of translators and interpreters to give substance to national language policies that call for language equity and multilingual language development. In South Africa, the Unit for Language Facilitation at the University of the Free State successfully trained interpreters for the Truth and Reconciliation Commission in Cape Town, 1995–1998. However, without foreign aid, this work cannot be sustained. There is also a need for extensive training of court interpreters, as many South African court proceedings are conducted in English and/or Afrikaans only, putting African language-speaking plaintiffs and accused at severe disadvantage. Judge J. Hlophe, in a public address, underscored the need for individuals to "receive justice in their own languages." It remains to be seen whether governments

can meet the demand for effective training of translators and interpreters in the African languages.

Language Learning and Teaching

The teaching of the excolonial languages in Africa has tended toward linguistic and cultural assimilation (Bamgbose, 1991). However, this has been largely unsuccessful due to inappropriate and ineffective Western-based teaching methods. These languages are often taught as if they were first languages, especially in Francophone and Lusophone Africa, with a heavy focus on grammar and with little regard for developing communicative ability (Webb and Kembo, 2000). This situation is exacerbated by the lack of natural exposure to these languages outside the formal teaching context. The communicative language teaching approach, introduced in Anglophone Africa, still has a Western bias in terms of expected behavioral norms, which are inappropriate and irrelevant in African contexts, with a disregard for "African discourse conventions and patterns of communication in language teaching approaches" (Webb and Kembo, 2000: 306).

Case studies of teachers in Eritrea, Namibia, South Africa, and Mozambique show that teachers use grammar-translation methods to teach the excolonial languages, with the emphasis on grammatical explanations and translation, often in the form of code-switching to the learners' home language. Where teachers have been exposed to more communicative methods in their pre- and in-service training, they tend to construe communicative activities as further exercises for oral work (Weideman, 2003), thereby fostering dependence on repetitious choral work, and rote learning (Macdonald, 1990; Taylor and Vinjevold, 1999). Resistance to an alternative language teaching methodology has been ascribed to various factors, including collusion to mask lack of proficiency (Chick, 1985); entrenched habits; and resistance to change through attitudinal factors (Weideman, 2003; Wildsmith, 1992). Despite interventions to increase exposure to the languages, such as *Learning English by Radio: The Mozambique Project,* in collaboration with *Radio Mozambique* in 1994, learners do not learn these languages sufficiently well to use them either as languages of instruction or to increase access to information in the public domain.

Because the ideology behind the learning of the excolonial languages in Africa, and English language teaching (ELT) in particular, has generally been assimilationist, one standard variety has been accepted as the norm to be attained. However, this may not always be an appropriate target for African learners of English, where students and teachers often bring their own Africanized variety to the learning experience. This variety tends to be transferred from teachers to learners in formal learning contexts where there is seriously reduced target language input. South African researchers have identified such a variety of English as Black South African English (BSAfE), and vigorous debates have ensued as to its acceptance as a language of learning (De Klerk and Gough, 2002; Anthonissen and Gough, 1998). This has a number of implications.

First, accepting BSAfE in the classroom might be perceived as a further form of disempowerment, as learners would not be encouraged to master the standard variety. Second, it would challenge the status of the African languages, which are currently being developed as languages of learning in South Africa. Third, there are many localized varieties subsumed under the label BSAfE, some of which are being developed into sub-corpora (e.g., isiXhosa), to eventually form a comprehensive corpus of BSAfE (De Klerk and Gough, 2002). There is thus no single variety known as BSAfE which could be restandardized (Wright, 1996) for educational purposes. Further information on the linguistic composition of BSAfE and the standards debate is provided in De Klerk (1996) and Mesthrie (2002). Research into attitudes toward English, its forms and its functions in various African countries, is covered by Schmied (1991).

Language Learning and Teaching: African Languages

The question of a standard variety also applies to the learning and teaching of African languages. It is a complex issue, as their development reflects different histories and different methods of standardization across the continent. In South Africa, the initial development of these languages was done by the erstwhile language boards, which often adopted a purist rather than a pragmatic approach to the development of a standard variety, which has been challenged as contrived, as it does not reflect actual community language use (Anthonissen and Gough, 1998). This adherence to a standard variety also affects language teaching methods, as a rigid, grammar–translation approach is commonly used, resulting in a sound knowledge of linguistic rules but little or no communicative proficiency. This seems to be the *status quo* in many African classrooms (Webb and Kembo, 2000).

In South Africa, there have been attempts to revise mainstream African language curricula and teaching methodology at both secondary and tertiary levels to reflect a more communicative orientation. However, the problems encountered with this type of innovation are similar to those encountered for English language teaching. In addition to resistance

to new methods by African language-teachers in schools, non-African language teachers, who are professionally trained to use these methods, often do not have the level of language proficiency required (Wildsmith-Cromarty, 2003). However, various universities in South Africa have mounted language courses to teach African languages for basic functional purposes in the workplace, using communicative methods. One such course is run by the University of KwaZulu-Natal in partnership with Yale University, for foreign students from America who take isiZulu as a credit toward their degree. A course in Northern Sotho, offered at the University of the North, includes a teacher training component for the language tutors, which requires them to critically reflect on their praxis, as well as to teach the language. This need for greater reflexivity on the part of language teachers is in line with a postmodern perspective on language learning and teaching, and is becoming more evident in teacher education courses in South Africa.

Academic Literacy Development in Higher Education

Much applied linguistic work has been directed toward English language and academic literacy development at tertiary institutions in Southern Africa. In the postmodern era, there seems to have been a shift from a problem-oriented, deficit approach, where non-English speaking students were perceived as limited in English proficiency and underprepared (Chimbganda, 2001), to a more constructivist approach which takes account of the student's own subject positioning and voice *vis-à-vis* academic discourse (Thesen, 1997; de Kadt and Mathonsi, 2003). The deficit perspective resulted in skills-based programs that were mainly adjunct, and packaged as language-bridging courses. The focus was on developing academic reading and writing skills for learning in other course subjects, so that assessment in these courses was mostly formative. The problem with these courses is the perceived lack of relevance by students, especially where the content does not form part of the mainstream curriculum (Chimbganda, 2001).

More recent South African approaches to teaching academic literacy include an integrated approach in which reading and writing skills are no longer decontextualized, but linked, instead, to the content of the disciplines. This is the approach taken at the University of KwaZulu-Natal where the scaffolding is done collaboratively between the academic literacy specialists and the subject specialists. The other approach works within a critical discourse analysis (CDA) framework (Janks, 1992; Thesen, 1997) and takes an academic-literacies perspective which locates research and practice within the ideological context of the particular institution. Crucial issues considered within this framework are "ownership of knowledge construction" (De Kadt and Mathonsi, 2003), identity, where discourse is perceived as contributing to the construction of social identities and subject positions, and voice (Thesen, 1997; Angelil-Carter, 1998). This approach is learner-centered, focusing more on the reader's role in interpreting texts. Students are encouraged to use their own experience as a base for critical commentary, and to construct their own interpretation of texts, which, in turn, creates a sense of agency. This is a move toward a more politically engaged applied linguistics in Southern Africa (Kapp, 2001: 14). Further information on writing practices at tertiary level, academic discourse and cultural diversity, accessing and acknowledging sources, feedback and assessment, writing pedagogy, and critical reading practices can be found in Leibowitz and Mohamed (2000) and Angelil-Carter (1998).

Because students bring to the learning experience a primary language or a variety of English not normally used for instructional purposes, they experience alienation from the discourses of the institution and of the disciplines. Yet, they wish to learn through the medium of English, even though the provision of academic literacy modules in English only runs counter to the expression of an African identity and voice within African tertiary institutions. Allowing students to learn and express themselves through their primary languages allows them to access sociocultural ways of knowing that are deeply embedded. It also constructs the primary languages as rich sources of knowledge, which can facilitate learning. This has major implications for the development of the African languages to carry academic content, and is an area that needs serious engagement by African applied linguists in the future.

There is still, however, a wide gap between the demands of the school curriculum and those of the university. Language teaching at school level does not provide learners with adequate cognitive academic language proficiency in either English or the primary languages. It is difficult to encourage critical reflection without the basic ability to read and write. This is one of the main areas of weakness in applied linguistics research in Africa.

Literacy

Literacy is crucially important for social emancipation, especially in African countries, which, until

the 20th century were more preliterate than most Western counterparts.

Reading Levels and Literacy Measures

Country-by-country valid and reliable literacy measures and estimates of reading levels in Africa are not available in data that would characterize, generally, continental African literacy levels. Data from three reliable sources, however, give some indication of reading and language proficiency levels within the context of overall educational quality assessment surveys. The Program Analysis of Educational Systems of the Conference of Education Ministers of Francophone Countries (PASEC), the Monitoring Learning Achievement Project (MLA), and the UNESCO-based Southern African Consortium for Monitoring Educational Quality (SACMEQ) all independently found overall low levels of reading and language proficiency in both Anglophone and Francophone African countries.

The PASEC study revealed language proficiency in French to be 65.1% in Cameroon, 43.5% in Senegal, with Burkina Faso, Cote d'Ivoire, and Madagascar scoring in the range 50–58%. In Madagascar, good performance in Mathematics and French "seem to confirm the hypothesis that learning in the native language . . . (Malagasy) . . . acts as a real accelerator in learning foreign languages" (Sylla, 2004).

The MLA study found "significant variations among countries and disciplines in reading levels, life skills, and arithmetic, with Year 4 performances generally low" (Saito, 2004). For example, the average pupil reading scores in 12 Southern and Eastern African Countries against a SACMEQ norm of 500 (SACMEQ Study II, 2000) reveal that only seven (Seychelles, Kenya, Tanzania, Mauritius, Swaziland, Botswana, and Mozambique) scored minimally higher than the SACMEQ norm, the Seychelles scoring the highest at 582. The other five countries (Uganda, Lesotho, Namibia, Zambia, and Malawi) scored below 500, with the lowest, Malawi, at 429.

The above scores were derived from 8-level reading tests, which measured pupil reading levels at Grade 6 against minimum skills levels, as defined "independently by the authorities in each country." (ADEA, 2004, 10). In effect, these results show that a large number of pupils at Grade 6 level were reading *de facto* at Grade 3 or 4 levels only.

Adult Literacy

The low educational levels of many adult Africans and the current high attrition rate from schooling together contribute to high levels of adult illiteracy. The PASEC survey referred to above found that the proportion of adults who can read easily after six years of schooling is generally low throughout Francophone Africa. If this is true of Africa generally, there would seem to be a high regression from school-achieved literacy. Retention of school pupils to Grade 12 is an ideal not easily achieved in Africa as yet, and literacy levels will remain low until this ideal is attained. The question of adult literacy, especially in the workplace, is considered in depth by Prinsloo and Brier (1996).

Early Literacy Development

Western cultural agencies and publishing interests have ensured a good promotion and supply of reading and learning materials which privilege the Western languages. This has served to devalue the status and currency of the few materials written in the indigenous languages. Control over one's mother tongue is more likely to ensure successful control over an additional language. However, this has been largely ignored in many African contexts, with the result that many African preschool and primary level children are denied the basic right to acquisition of literacy in their mother tongue (Bloch, 1999).

Enliteration: Challenges and Responses

Both early childhood and adult literacy development present high priority challenges to applied linguists wishing to contribute to language development and effective, communicative, multilingual use of languages, both primary and additional (Western) languages. This requires urgent attention to the role of the mother tongue in first and second language enliteration processes. Three Southern African-based responses are worth mentioning here.

The Molteno project, based in Johannesburg, has achieved considerable success in training and retraining teachers using an additive bilingualism model that draws on teachers' first language resources to enable them to teach English as an additional language.

Concept literacy is the goal of a major project involving the Universities of Cape Town, KwaZulu-Natal, and Rhodes. Based at the Center for Applied Language and Literacy Studies and Services in Africa (CALLSSA), this project seeks to provide a textual resource base of mother tongue equivalents of English medium core concepts in Math and Science at Grades 1–9 levels, to assist teachers and learners to overcome the barriers of language and concept formation in the new South African curriculum.

Finally, the Project for the Study of Alternative Education in South Africa (PRAESA), working in multilingual education, has initiated a program of biliteracy at Grade 2 level. Children learn to read and write in both isiXhosa and English simultaneously,

so that they do not lose the emotional creativity and potential for literacy that comes with learning through the mother tongue (Bloch, 1999). In addition, there is a move to revive the strong African oral tradition, with its rich folklore and story genres, so that literacy practices may arise naturally from orality.

Conclusion

At the turn of the millennium, applied linguistics in Africa was becoming indigenized, in keeping with the ideological focus on linguistic diversity, language development, and multilingualism. There is a strong call for community participation in research at all levels – an emic perspective which will help inform decisions on language varieties versus language standardization, pedagogic practices, and language practices in key domains. Linguistic and sociocultural diversity is being foregrounded, as the hegemony of excolonial languages is increasingly challenged, giving rise to research truly characteristic of an African postmodern context. In keeping with the emphasis on social justice and equity, Africa needs to promote expertise in African language development, including translation, lexicography, terminology, interpreting, creative writing, and journalism. There is need for a focus on bilingual and multilingual language learning in teacher education programs, and increased professionalization of language teachers at all levels of education. Finally, there is a need for more research into legal, medical, and business discursive contexts, where intercultural communication is so crucial. This needs to happen, however, from an *African* applied linguistic perspective, in support of the formation of a truly African identity and the need for social accountability.

The Domain of Applied Linguistics in the Region

The domain of applied linguistics is contested worldwide; the region of Australia and the Pacific is no different. Applied linguistics is seen in a variety of different ways, the broadest view being that of the Australian Applied Linguistics Association, whose website states its goal as the application of linguistics to

- the methodology of teaching, learning, and testing languages (mother tongue and foreign languages);
- multicultural education in Australian society, including aboriginal, migrant, and other groups;
- language teaching technology;
- problems of language and the individual (including language acquisition and dysfunction);
- problems of language and society (including language planning and language standardization);
- the theory and practice of translation;
- the analysis and interpretation of spoken and written discourse (including stylistics, poetics, and pragmatics);
- the study of language in relation to other semiotic systems (including film and theatre, mime and dance, codes and ciphers, costume and ornament, mythology and folklore).

A scan of university departments and their degrees offers a different perspective. Macquarie University, for example, offers a Masters degree in applied linguistics, with four strands: general, literacy, TESOL (teaching English to speakers of other languages), and language program management, while other degrees cover many of the topics above. For example, language dysfunction is the subject matter of a number of degrees in speech and hearing, while interpreting and translation have degrees under their own name. The University of Melbourne, on the other hand, includes four different strands under the rubric of applied linguistics: computer-assisted language learning, English language, language testing and language program evaluation, and TESOL. The University of Auckland has a Department of Applied Language Studies and Linguistics, with programs in

Applied Linguistics in Australasia and the Pacific

D E Murray, Macquarie University, NSW, Australia

The Domain of Applied Linguistics in the Region

The domain of applied linguistics is contested worldwide; the region of Australia and the Pacific is no different. Applied linguistics is seen in a variety of different ways, the broadest view being that of the Australian Applied Linguistics Association, whose website states its goal as the application of linguistics to

- the methodology of teaching, learning, and testing languages (mother tongue and foreign languages);
- multicultural education in Australian society, including aboriginal, migrant, and other groups;
- language teaching technology;
- problems of language and the individual (including language acquisition and dysfunction);
- problems of language and society (including language planning and language standardization);
- the theory and practice of translation;
- the analysis and interpretation of spoken and written discourse (including stylistics, poetics, and pragmatics);
- the study of language in relation to other semiotic systems (including film and theatre, mime and dance, codes and ciphers, costume and ornament, mythology and folklore).

A scan of university departments and their degrees offers a different perspective. Macquarie University, for example, offers a Masters degree in applied linguistics, with four strands: general, literacy, TESOL (teaching English to speakers of other languages), and language program management, while other degrees cover many of the topics above. For example, language dysfunction is the subject matter of a number of degrees in speech and hearing, while interpreting and translation have degrees under their own name. The University of Melbourne, on the other hand, includes four different strands under the rubric of applied linguistics: computer-assisted language learning, English language, language testing and language program evaluation, and TESOL. The University of Auckland has a Department of Applied Language Studies and Linguistics, with programs in

linguistics, language teaching and learning, and TESOL.

If applied linguistics is concerned with applying our knowledge about language to real-world decision making, then the discipline includes the broad areas of language in education, language in the workplace, and language in social life. While language, and therefore its study, linguistics, appears to be the core knowledge base of applied linguistics, it is necessarily interdisciplinary in nature, drawing on disciplines as different as psychology, education, sociology, computer science, and philosophy. However, it is neither linguistics nor an interdisciplinary mélange that is the emphasis of applied linguistics; rather, it concerns issues and the research on and solution to language-related problems that people encounter in the real world, whether those people be policy makers, lawyers, doctors, teachers, or interpreters. Further, applied linguistics is not simply the application of knowledge of language to issues of language use; increasingly, applied linguists study the very practice of language in use in real-world situations, leading to theorizing that itself contributes back to linguistics and other fields. This article then takes the view that applied linguistics is itself a discipline that uses a variety of disciplinary tools to analyze language in use, constructs theories from such research, and contributes to new knowledge in linguistics and other disciplines. It looks, therefore, at both the research/theory building and the practice of applied linguistics within the region. This position is not uncontroversial, as linguists within Australia, working in the systemic functional linguistics paradigm, have asserted that linguistics by its very nature is social, responsive to community need, and interventionist and so there is no need for the term applied linguistics (Painter and Martin, 1986). While this article is organized under the three broad issues mentioned above, they do, of course, overlap. All three areas by their very nature of referring to real-world problems require an understanding of the professional practice under investigation. Therefore, "If applied linguistics is truly problem driven, then it needs to be equally outcome focused, and collaboratively undertaken with professional practitioners" (Candlin and Candlin, 2003: 146). As we discuss below, much of the applied linguistics research in Australasia has been collaborative and focused on problem solution.

The World of Australasia and the Pacific

The Macquarie Dictionary, the authoritative source of Australian-English usage, defines Australasia as "Australia, New Zealand, and neighbouring islands of the South Pacific Ocean" (Delbridge *et al.*, 2001: 117). In one sense, this definition makes the title of this article repetitive; however, for those not familiar with the term, it may explain the region under discussion. For the purposes of this article, the region is confined to the Macquarie Dictionary definition of Australasia, that is, islands in the Pacific region not in the neighborhood of Australia and Aotearoa/New Zealand will not be included (for example, Guam).

The World of Applied Linguistics in the Region

Research and practice of applied linguistics in the region, as in any other region, draw on a variety of research and linguistics paradigms; however, this region is unique in that one particular theory of language has dominated the discipline in the latter half of the 20th century, namely, systemic functional linguistics. This framing began with the appointment of Michael Halliday to the Chair of Linguistics at Sydney University in the late 1970s and the subsequent development of the Sydney school of genre, which has been influential in applied linguistics throughout the region and beyond (for example, Singapore and Hong Kong SAR (Special Administrative Region)).

Language in Education

In many journals and articles, applied linguistics is synonymous with second language teaching; however, the real-world language-related problems in education include literacy, mother-tongue education, language teacher preparation, and languages for specific purposes, as well as additional language education (whether as a second or foreign language). While accepting that the dichotomy between second and foreign language cannot be upheld either theoretically or descriptively, it is a useful shorthand (*see* **Second and Foreign Language Learning and Teaching**).

The influence of systemic functional linguistics can especially be seen in research and practice in language and education, an influence that cuts across all levels of education. One of the primary characteristics of this approach is the description of genres, that is, the culturally typical ways of engaging rhetorically with recurring situations. The Sydney school, as well as following a specific, social model of language, has promoted pedagogical approaches to provide access to the genres of power for learners other than the brightest, middle-class monolingual students (Martin, 1989). This has led to explicit instruction in the features of specific genres for specific learner

groups, for example, recount for young learners and adults new to English or even literacy, or report for secondary science students, or thesis writing for tertiary students. This instruction follows a teaching–learning cycle with the following characteristics:

- building the context, during which teacher and learner explore the sociocultural context of the text type or genre being studied
- modeling, during which teacher and learner read sample texts and analyze and discuss their language and structure
- joint negotiation of text, during which teacher and learners construct a text together
- independent construction of text, during which learners write their own texts, consult with their teacher, and finally redraft and edit
- linking to other texts, during which teacher and learners explore other texts in similar or different contexts (Callaghan and Rothery, 1988).

Literacy Literacy within applied linguistics has been variously defined; however, the approach taken here is one that goes beyond reading and writing as skills but that includes the sociocultural construction of literacy, including visual literacy. Literacy has been extensively researched in the region at primary, secondary, adult, and tertiary levels; however, the research has not always been conducted by applied linguists and, in Australia in particular, there has been considerable tension between literacy researchers and applied linguistics researchers, between proponents of process writing and whole language and proponents of explicit modeling, and between views of literacies as socioculturally constructed, as cognitive-psychological skills, as reading and writing, or as entailing four competencies, namely, coding, semantic, pragmatic, and critical. The cognitive-psychological approach (for example, Coltheart, 1980) has had particular research application in the area of reduced literacy skills in children and adults with cognitive dysfunction, with particular focus on reading of individual words. Work in second language learning has also shown that growth of vocabulary is one of the more, if not most, important aspects of second language learning. In contrast, a study in Fiji, where reading for pleasure is not part of the culture, found that immersing learners in a 'flood' of extensive reading positively affected reading and listening comprehension, as well as related skills (Elley and Mangubhai, 1981). However, literacy education remains a key priority in Fiji, as in other Pacific nations that have jointly signed on to the Basic Education and Literacy Support Program, in conjunction with the United Nations Educational, Scientific and Cultural Organization (UNESCO) and other aid agencies. Delivery of such programs is complicated in Fiji because of its history of local, community-based, controlled education system. While Fiji is often praised for its decentralized system because it meets local needs, attempting to implement a nation-wide program is difficult. The 1991 policy document that established the Australian Language and Literacy Policy (ALLP) (Department of Employment Education and Training, 1991) defined literacy in such a way that it became equated with English, language, or even oracy and defined literacy as merely functional. Across education sectors, English as a second language (ESL) teachers considered themselves to be language teachers, and that language included literacy. However, these practitioners acknowledged the important distinctions between mother tongue and additional language acquisition, a distinction lost in the ALLP definition and subsequent provision. The view that second language education and literacy are distinct fields has also been advocated in New Zealand. This conflation of terms led to disputes over research funding and service delivery, but more importantly, has also led to the almost invisibility of ESL (and English as a second dialect (ESD)) in many sectors, as it is subsumed into generic literacy programs, although many states in Australia still maintain Intensive English Programs as centers specializing in English as an additional language (EAL) instruction for recent arrivals of high school age. Most recently, there has been a move to change qualifications of teachers teaching in the technical and further education sector (largely vocational education) within Australia, so that the qualification for teaching a second language be a diploma in language, literacy and numeracy, and that holders of such a diploma be able to teach ESL as well as literacy and numeracy to native English speaker adults. Currently, Australia and Aotearoa/New Zealand have no official literacy policy on which to draw.

Within the vocational and training sector in Australia, there has been recent discussion about appropriate models of delivery of literacy (and numeracy): fully integrated, isolation, and shared responsibility. Fully integrated models are those in which there are no specialized literacy instructors or curriculum, but literacy is embedded in training packages. In the isolation model, literacy specialists provide support for learners through independent programs and curricula. The shared responsibility model, the one favored by the sector, blends the two extremes so that literacy specialists provide specialized literacy instruction, but vocational subject matter instructors also share some of the

responsibility for the literacy development and referral of their students.

In Aotearoa/New Zealand, while there is debate between whole language and a more cognitive approach to early literacy, literacy has a wide definition within the schooling sector – not merely reading and writing, but also uses of language valued by society, individuals, and communities. New Zealand research has found that some groups (for example, Samoan and other Pasifika communities) are not well served by schools because there is a mismatch between community and schooling literacy practices (McNaughton, 1995). Others have found that non-English speaking background (NESB) learners were behind their peers in literacy, mathematics, and logical problem solving (Wylie *et al.*, 2001) and that teachers perceive that it is students' own characteristics that affect their ability to learn English (Kennedy and Dewar, 1997).

Mother Tongue Education While literacy may be subsumed under mother tongue education, it was dealt with separately above because of its salience in public discourse. Because the region under discussion includes countries with multiple languages, either indigenous or immigrant, the language of education is a contested issue. Papua New Guinea, for example, with over 850 languages, has embarked upon education reform, with the children's vernacular used in the early primary years, a transition period during which both the vernacular and English are used, and upper primary, where English is the language of instruction. However, research (Honan, 2003) has shown that, because of the number of languages and the mobility of families, the vernacular taught in a child's school may not be the vernacular used by the child. The child's home language may in fact be Tok Pisin, one of the three official languages of Papua New Guinea, not the vernacular of either parent. Additionally, while the vernacular may be the home language for some communities, it may not be the language for literacy practices. The language planning assumption seems to be that through mother tongue education, a community of literacy practice will develop in that mother tongue; however, the only opportunity for literacy practices may be in one of the official languages – for completing forms, reading the contents of packaged goods, and so on. While education has used the vernacular in Papua New Guinea and several other former British colonies such as Fiji (initially by missionaries for evangelism), Samoa, and the Kingdom of Tonga, English was used for education in the Solomon Islands during the colonial period, supposedly because of the large number of languages (today around 80) used by the small population (today about one-third of a million), and today is the official language, although Solomon Islands Pijin is a *lingua franca*. In the Solomon Islands, the Pijin word for 'one language' is used to describe one's extended family, all being speakers of the same language. Tonga maintains a strong tradition of literacy in Tongan and English as an additional language and, unique among Pacific Island nations, has universal primary education. Its strong religious focus as a nation has encouraged Tongan literacy for Bible reading and English as a language for wider communication. Almost all Tongans are literate in either or both languages. In Samoa, Samoan is the national language and children are educated in it; English is used officially for business, a result of its long association with New Zealand, having been a mandated and then trust territory of New Zealand for almost 50 years after World War I.

In Australia, English-only instruction was policy for Australia's indigenous peoples, Aboriginals and Torres Strait Islanders, until the early 1970s (except for some Christian Mission schools), when the government of the time considered that every Australian should be literate in their first language (L1) first, leading to bilingual schools in a number of states and territories. However, by the 1990s, the only extant bilingual programs for indigenous peoples were some run by individual states. What is important to note is that Aboriginal languages were not written until the 19th or 20th centuries, so the transition from an oral to a literate culture has been quite recent in comparison to the cultures from which the majority of Australians come. Additionally, most Aboriginal adults in remote communities speak English as a second (or more) language, while their children start school speaking an indigenous language. These children therefore acquire literacy first at school in English. In cities and rural centers, children (and adults) will often be speakers of Aboriginal English so that acquisition of standard Australian English, with its different linguistic features at the word, sentence, and text levels, needs to be explicitly taught; this is not always the case, however. Additionally, language and literacy education needs to be culturally appropriate and to use learning strategies compatible with indigenous learning styles. One such effective and well-researched program has been operating in Western Australia for several years as a collaboration between university-based and community-based researchers (Malcolm *et al.*, 1999).

In Aotearoa/New Zealand, grass-root (usually called flax-root after flax, a native plant in Aotearoa/New Zealand) initiatives in the early

1980s led first to the development of Te Kohanga Reo, preschools in Maori in which grandparents transmitted language and culture to their grandchildren, bypassing parents who are mostly not native Maori speakers. Later, the Kura Kaupapa Maori movement developed strict criteria for their schools, which included only teachers who are fluent native speakers of Maori and immersion for youngsters for 6 years. Research has shown that Maori and Pasifika languages are supported at early childhood level and there are some immersion and bilingual classes in primary schools but virtually no support at the secondary level (David *et al*., 2001).

For mother tongue education for students whose families use community languages (community language is used in Australia for the languages of immigrant communities), this education has primarily relied on community language schools, although many community languages are taught in schools and, in Australia, increasingly in the primary school. Many state governments provide financial support and free access to government school premises for community language schools. In Australia, many of these languages are examinable at end-of-high-school gate-keeping examinations so that learners from different community languages can count their mother tongue competence for graduation requirements. Bilingual education is not as prevalent in Australasia as it is in the United States, for example, largely because there is seldom a critical mass of learners of the same language at the same age level. The exception is Australian Sign Language (Auslan), for which there are schools specifically for learners with hearing loss. However, as more and more children have cochlear implants and are mainstreamed, there is some fear that Auslan is becoming an endangered language.

Language Teacher Preparation and Professional Development While there are many language teacher preparation programs in the region, there is no coherent body of research into teacher knowledge and skills required for effective language instruction. Some recent research has focused on the role of the non-native teacher and teacher candidate. There has, however, been a long tradition, especially in the adult ESL field in Australia, of teacher-conducted action research (for example, Burns and de Silva Joyce, 2001), which has examined a variety of different teaching and learning issues, from vocabulary instruction to using computer-mediated communication in the language classroom to learner-centered curriculum, always with the goals of both the professional development of teacher–researchers and the improvement of instruction in mind.

Languages for Specific Purposes While English for specific purposes, especially at the tertiary level, is well researched in the region, there is little research on the use of languages other than English (LOTE) for specific purposes, largely because English is the primary medium of communication in the region. Much of the work has been completed using the systemic functional linguistics model of language to describe the discourse of disciplines such as sociology, geography, science, and social studies (for example, Halliday and Martin, 1993). Other work includes English for academic purposes (EAP) (Kaldor *et al*., 1998), contrastive rhetoric, scaffolding, and genre studies.

Additional Language Education As a result of Australia's 1987 *National Policy on Languages* (Lo Bianco, 1987), Australia developed initiatives for the teaching of LOTEs, both languages of ethnic communities and languages of trade or tradition. Since their introduction, research has been conducted to examine all aspects of the use and learning of these languages. Such studies have shown that different levels of attainment are reached for different languages (Brown *et al*., 2000), that participation affects acquisition (Brown *et al*., 2000), that mother tongue affects classroom management (Clyne *et al.,* 1997), and that computer-based instruction may facilitate learning (Felix, 2001).

One thrust of research and practice in both LOTE and English language education in Australia has been the inclusion of culture in language teaching – not high culture or popular culture, but rather the way culture is transmitted through language. This has led to theories about and research into intercultural competence, an expansion of Hymes's communicative competence (Liddicoat and Crozet, 2000). This work has posited the notion of an intercultural space that educators need to help their learners develop, a space that other researchers refer to as fault lines or contact zones. This intercultural space is complex, requiring tolerance of ambiguity and negotiation of meaning.

Another theoretical thread through the research in both additional languages and language (especially English) for specific disciplinary purposes has been scaffolding, a strategy based on Vygotsky's zone of proximal development (1978). Research into scaffolding has identified both contingent and planned scaffolding (Hammond, 2001), that is, scaffolding that occurs *in situ*, as students interact with the teacher and jointly construct spoken and written texts, and scaffolding that is at the macro level, occurring through pre-planned selection and sequencing of activities and strategies.

While the genre approach discussed above under language in education focuses on language as text, written or spoken, considerable research has also been conducted in both Australia and New Zealand into the teaching and learning of individual skills, such as casual conversation, vocabulary, grammar, and pronunciation.

Although Aotearoa/New Zealand is an immigrant nation, most immigrants came from English-speaking countries, except for a large wave of Pacific Islanders in the 1960s and 1970s and Chinese and refugees in the last few years. For the former group, the Pasifika Education Plan was recently developed to cover all education sectors, with a focus on improving early literacy and provision of bilingual education. Recently, as a result of the growing numbers of second language learners in grade K–12, the New Zealand Ministry of Education commissioned research into best practices for delivering ESOL services to new immigrants and developed an adult ESOL strategy (Ministry of Education, 2003).

Language in the Workplace

Language in the workplace encompasses workplace communication as well as the discourse of the profession, extending even to forensic linguistics. There is a strong tradition of research into health care communication, especially in intercultural contexts (for example, Dowell *et al.,* 2001), and more general language use in the workplace, especially targeted for immigrants. In Australia, this included a televised program with accompanying workbooks. Forensic linguistics is a strong application of linguistic work in Australia (see, for example, Gibbons, 2003) and New Zealand and includes work on Aboriginal and NESB clients in the courts.

Language in Social Life

While language in social life could be a broad-ranging area covering many topic areas, within the region, language planning has had the most impact. However, translation and interpretation and language assessment have also been prominent in the region. While language assessment may appear to apply largely to language and education, within the region it has been used for broader social decision making, such as immigration and professional accreditation. Language education policies could arguably fall into language in education; however, since such policies involve interventions that affect the broader society, that is, not only educationalists and learners, it is best categorized and discussed under language planning more generally. Because another article considers language education policies in the Pacific (*see* **Language Education Policies in the Pacific**), this article is confined to language education policies in Australasia.

Translation and Interpretation Translating and interpreting became a recognized profession in Australia in the 1970s, with the establishment of the National Authority for the Accreditation of Translators and Interpreters Ltd. (NAATI), a company that determines the levels of competence expected of professionals and that also accredits training programs, from which graduates are automatically certified. NAATI is the official organization for such testing and accreditation in both Australia and New Zealand.

Language Assessment Language assessment covers a broad range of both achievement assessment of language learning and high-stakes tests for accreditation, immigration, and placement into educational programs. In Australia, within the Adult Migrant English Program (AMEP), there has been more than a decade of research and development of assessment of adult migrants' competency as a result of instruction in AMEP language programs. This research has investigated task comparability and difficulty, rater consistency, washback, and task moderation (for example, Brindley, 2000). The overall goal of the program has been to provide professional development for teachers to be able to assess their learners themselves reliably. Within the school sector, there has been research into oral assessment of NESB adolescents.

One line of research has been into the IELTS (International English Language Testing System) examination, the test used for university entrance of international students, immigration, and entrance to some professions. Research covers most areas of test design and implementation, from task difficulty to predictive validity to reliability.

Another form of assessment has been the benchmarking projects in Australia, projects designed to determine learner pathways for NESB learners in Australian schools (McKay *et al.,* 1994). More recently, the government has developed a national Literacy and Numeracy Plan, with reports on all learners against benchmarks, disaggregated for language background. There is no equivalent in Aotearoa/New Zealand; however, there are the New Zealand Curriculum statements of expected achievement and NESB assessment guidelines. Both, however, are benchmarked against native speaker students.

Language Planning and Policy Australia is unique in the English-dominant world in having developed an extensive and inclusive national policy on languages

in 1987 (Lo Bianco, 1987). This policy included policies in three main language arenas:

1. English for all
2. Aboriginal and Torres Strait Islander languages
3. A language other than English for all.

It thereby affirmed English as the national language with three types of provision: first language acquisition, acquisition by immigrant adults and children, and English as a foreign language (EFL), which was to include Aboriginals who have little exposure to English use in their daily lives learning English, assistance in the form of foreign aid, and a regional provider for international students and guests. In the arena of Aboriginal and Torres Strait Islander languages, the policy provided for bilingual education programs, translating and interpreting services, English and literacy programs, national awareness of these languages, and support for and revitalization of these languages. In the arena of LOTEs, languages to be taught included community languages for both maintenance (such as Maltese) and new learning (for example, Greek), as well as programs for languages of importance to Australia for trade (for example, Japanese and Indonesian) or historical reasons (for example, French).

Prior to the adoption of the National Policy, Australia had legislated a national program for the teaching of English to adult immigrants and refugees. This national program (see Martin, 1999 for a history of this program), begun in 1949, is a settlement program, funded through the Department of Immigration and Multicultural and Indigenous Affairs. Unlike the teaching of the official language to immigrants in many other nations (for example, the United States, Great Britain, and New Zealand), Australia's program is both national and highly integrated, containing features unique to Australia, such as a national curriculum framework, a national research center to coordinate and conduct research and professional development across the program, highly professional teachers, and a collaborative approach between the Commonwealth and organizations providing the program.

In Aotearoa/New Zealand, the 1987 Maori Language Act established both English and Maori as official languages, with the Maori Language Commission established to oversee programs promoting indigenous language. In the early 1990s, Aotearoa/New Zealand attempted to develop a national language policy and in 1992 published a draft document, which was, however, never ratified or implemented. In the meantime, various government documents created a *de facto* if not a *de jure* language policy. Such documents include ones referred to above for language in education, as well as statements within the New Zealand Curriculum Framework, which recognizes English as the language of national and international communication, but also acknowledges that students from language backgrounds other than English (LBOTE) should initially use their first language and move between it and English, and that such students should also develop and use their own language as part of their schooling.

One of the more interesting language-planning initiatives in the region has been in East Timor, since its liberation. Like much of the region, the language situation is highly complex, with 15 indigenous languages (Tetum [Tetun], the vernacular of the Belu who united central Timor under their rule, being the most widely spoken), two colonial languages (Portuguese and Indonesian), and one language of wider communication, English. The new government chose Portuguese as the national language of the new nation, because the Portuguese influence on East Timor is reflected in their views of themselves as a nation and their common ethnic consciousness and unity.

Introduction

The People's Republic of China (PRC) is a country in which 56 ethnic groups (or nationalities) are officially recognized. The majority ethnic group, the Han Chinese, accounts for 91.6% of the total population, which is estimated to be approximately 1.27 billion on the China mainland alone and 1.3 billion for the 'Greater China' region, which includes the populations of Hong Kong, Macao, and Taiwan (National Bureau of Statistics of the People's Republic of China, 2001). On the China mainland, around 8% of the population are members of 55 minority groups, many of which have retained their own languages. The Han Chinese people speak two main groups of dialects: the northern dialects and the southern dialects. The northern dialects can be subdivided into seven subgroups, and the southern dialects into six subgroups (Huang, 1987: 33–45). Among the 55 minorities, it has been reported that as many as 80–120 languages are spoken (of which 60 are officially recognized) (Zhou, 2003: 23), and that these minority languages also show a significant amount of dialectal variation.

After the establishment of the People's Republic of China in 1949, it took a few years for an official language policy to be formulated, but since 1956, the government language policy has been the 'unification of the Chinese language' and the promotion of *Putonghua*, the 'common language' based on the northern dialect and the Peking pronunciation. Other language-planning aims have included the removal of illiteracy, the propagation of simplified characters, and the promotion of the official romanization system of pinyin. Following the establishment of the republic, ethnic minorities were initially allowed to use and develop their languages, but their languages were suppressed during the Cultural Revolution (1966–1976); afterward, they were encouraged to become bilingual in their own languages and Chinese. Since 1949, various foreign languages have been taught in China at different times, and the learning of Russian has been considered to be of prime importance. Since the late 1950s, however, with the exception of during the Cultural Revolution, English has been regarded as the most important foreign language to learn. Other foreign languages of secondary importance include Japanese, German, French, and other languages for diplomatic purposes. At Beijing Foreign Studies University (BFSU), for example, over 30 foreign languages are currently taught.

Although applied linguistics can be dated back to the 1940s in the United States (Kaplan, 2002: vii), applied linguistics as a recognized discipline did not begin to establish itself in China till the late 1970s, at the end of the Cultural Revolution. Nevertheless, it can be claimed that applied linguistic issues and practices were part of the Chinese experience long before the term *yingyong yuyanxue* ('applied linguistics') came into use. This article begins with a brief review of the recent history of China and a summary of the development of linguistics in China. It then proceeds to a discussion of applied linguistics, with reference to the study of three types of language issues in China, concerning the Chinese language, minority languages, and foreign languages.

Historical Background

It is generally accepted that the Chinese have one of the oldest language traditions in the world, with a number of written texts dating back some 3000 years. Issues related to language have been at the heart of many of the key philosophical debates in Chinese intellectual history (Hansen, 1983). In addition, China has had a long history of classical lexicography dating from the work of Hsü Shen in the 1st century A.D. to the present (Wang and Asher, 1994). When the first Catholic missionaries under Matteo Ricci began to visit China from the late 16th century on, they were immediately impressed by the intellectual culture they encountered. The first pioneers of modern dialectology were arguably the Protestant missionaries who arrived from the early 19th century on. They were fired by the desire to map the dialects of China in the service of their churches and were keenly concerned with learning and codifying the vernacular languages of their constituencies, including the Canton dialect, Hokkien, and the Amoy (Xiamen) dialect (Bolton and Luke, 2005). A number of the Protestant missionaries were also convinced of the need for language reform, and their proposals included the vernacularization of the Chinese writing system, and the use of various romanized writing systems alongside or instead of Chinese characters.

Such early dialectological work was accompanied by the incursion of Western traders, diplomats, and missionaries into China. After the First Anglo-Chinese War (1839–1842) and the Second Anglo-Chinese War (1856–1862), a number of 'treaty ports' were established at such locations as Canton (Guangzhou), Amoy (Xiamen), Foochow (Fuzhou), Ningpo (Ningbo), and Shanghai. A system of missionary

schools was established in these and other locations, in which pupils were often taught English, which fast gained popularity as a language of commercial value. The Chinese authorities also began teaching English themselves and founded an interpreters' college, the *Tongwen Guan*, in Peking in 1862, followed by other foreign language schools elsewhere. Somewhat later, by the beginning of the 20th century, a system of English-medium colleges and universities had been established across China (Bolton, 2003).

Late-19th-century China was a time and place of rapid social and political change, as the country attempted to come to terms with social disturbances, the pressures of modernization, and contact with the West. In 1911, the last emperor of China was deposed, and a republic was declared the following year. The decades that followed were politically chaotic, with various nationalist (*Guomingdang*) and communist factions competing for power. In 1931, Japanese forces occupied Manchuria, and throughout the 1930s they fought against both the communists and nationalists for control of the country. After the defeat of the Japanese in 1945, the communists gained control, and the PRC was established on October 1, 1949.

The new government faced immense problems in rebuilding the economy and infrastructure of the country and in formulating its foreign policy. Initially, China's leaders aligned themselves with the Soviet Union, but from the late 1950s and early 1960s on, they began to move away from this stance. Following this distancing, there was renewed interest in English, but this was cut short by the Cultural Revolution (1966–1976). During this period, education was made subservient to politics at a time when economic and political turmoil resulted in a tremendous loss of lives. At the end of the Cultural Revolution, however, a number of important policy changes took place, including the resumption of university education and the launching of Deng Xiaoping's policy of 'Four Modernizations,' which soon evolved into a "reform and opening policy" (Dillon, 1998: 109). In the 1980s and 1990s, China industrialized rapidly and economic growth has now created substantial pockets of new wealth (at least for certain sectors of the population) and has assisted in the formation of a new middle class. On the international front, China joined the World Trade Organization (WTO) in December 2001 and will host the Olympics in 2008.

Modern Linguistics in China

According to Branner (1997: 244), before the late 19th century, the Chinese linguistic tradition was "almost entirely philological" in the sense that "it was concerned with how to read received classical texts (especially rhyming texts), how to read rare characters, how to manage the great wealth of canonical alternate readings for individual characters, and how to explain the graphic structures of characters." By the early 20th century, however, comparative linguistics in China had been advanced by the work of British scholars such as the missionary Joseph Edkins (1823–1905) and the consular official Edward Harper Parker (1849–1926), who was a pioneer in the collection of dialectological data (Branner, 1999). Such Western linguists contributed to the debates that took place on modernizing and reforming the Chinese language in the late nineteenth and early 20th century. After the establishment of the Chinese Republic in 1912, various groups of Chinese scholars pressed for the reform of the written language, which eventually resulted in the *baihua* movement of the 1920s and 1930s and in the emergence of modern standard Chinese (De Francis, 1950).

By the 1930s, a domestic tradition in linguistics and dialectology began to be established, associated with such scholars as Yuen Ren Chao (1892–1982), Fang Kuei Li (1902–1987), and Wang Li (1900–1986). By this time, linguists also began to classify Chinese dialects according to seven or eight major groups. Varieties such as the 'Shanghai dialect,' 'Amoy vernacular,' and 'Canton dialect' now came to be referred to as the *Wu*, *Min*, and *Yue*, a system of classification credited to Fang Kuei Li (Chan and Tai, 1989). All three scholars studied at Western universities: Chao took a Ph.D. in philosophy at Harvard (but also had extensive contacts with Edward Sapir, as well as Leonard Bloomfield and Roman Jakobson), Fang Keui Li studied linguistics in Chicago with Edward Sapir, and Wang Li read general linguistics and phonetics in Paris (Chan and Tai, 1989; Shen, 1994). In the 1920s and 1930s, many Chinese linguists, including Chao, became keenly involved in discussions on language reform and on such issues as a national phonetic alphabet, simplifying characters, and promoting literacy. Among nationalist politicians in the 1930s, however, the issue was how to 'unify' the language and the need for "one state, one people, one language" (De Francis, 1950: 84). After the establishment of the People's Republic in 1949, such goals resurfaced in various language planning initiatives, as discussed in the next section.

Linguistics Applied and Applied Linguistics in Contemporary China

In contemporary China, applied linguistics is broadly associated with three types of linguistic activities: Chinese language education, developing minority

languages, and the teaching of foreign languages, including English.

Applied Linguistics and the Chinese Language

In the post-1949 period, as noted above, a central tenet of official language policy has been the promotion of the spoken standard, Putonghua, and the codification and teaching of a standardized Chinese script. In 1954, the government initiated discussions on the simplification of Chinese characters, and in 1956, the First Character Simplification Scheme was implemented. After the Cultural Revolution, some attempt was made to increase the number of simplified characters, but it was not well received. In 1986, the 1964 list with 2235 simplified characters and 14 radicals (or parts of a character) was reaffirmed for general use. In tandem with the teaching of simplified characters, Putonghua has also been promoted as the standard spoken dialect in all official domains. In February 1956, the State Council issued a directive requiring all primary schools and secondary schools, except those in ethnic minority regions, to include the teaching of Putonghua in Chinese lessons from the autumn of 1956. If Chinese was taught in minority schools, then Putonghua should be used as a standard. To facilitate the learning of Putonghua, a romanized script, *Hanyu Pinyin*, was finalized in 1958. Training workshops were organized for teachers, but this initiative was interrupted by political events and the Cultural Revolution. From the mid-1980s, much effort was spent in developing assessment instruments, culminating in the *Putonghua Shuiping Ceshi* (PSC or Putonghua Proficiency Test) for native speakers of Chinese, which was implemented widely from 1994 and formally endorsed again in 1997 by the State Language Commission. Another test designed for nonnative speakers of Chinese, the *Hanyu Shuiping Kaoshi* (HSK or Chinese Proficiency Test of China) was also established by 1988. The Hanyu Shuiping Kaoshi is now internationally accepted as the standard test for Chinese as a Foreign Language (Gu, 1997; Lam, 2005).

Another notable area of applied Chinese linguistics has been that of machine translation. As early as 1956, a machine translation project team was established at the Chinese Academy of Sciences. The initial work involved translation between Chinese and Russian. The focus was later changed to multilingual systems based mainly on translation protocols between Chinese and English. This machine translation research group later evolved into the Applied Linguistics Research Laboratory: Chinese Academy of Social Sciences, 2002.

Although the effect of linguistics on language planning and Chinese studies can be traced back to the late 19th century, as mentioned earlier, it was not until 1980 that the *Zhongguo Yuyan Xuehui* (Society of Chinese Linguistics) held its inaugural meeting. In January 1984, the *Yuyan Wenzi Yingyong Yanjiusuo* (Applied Linguistics Research Institute) was established under the auspices of the Chinese Academy of Social Sciences and the *Zhongguo Wenzi Gaige Weiyuanhui* (Commission on Language Planning of China), and in September of the same year, the institute held its inaugural conference. In 1985, at the first international conference on the 'Teaching of Chinese,' held in Beijing, it was proposed that an association for the teaching of Chinese should be established worldwide. In 1990, a symposium was held jointly by the Applied Linguistics Research Institute and Suzhou University to explore issues such as the scope of applied linguistics and its relevance for language teaching and language standardization. Two leading journals in applied Chinese linguistics are *Yuyan Wenzi Yingyong* (Applied Linguistics), which was first published in 1992, and *Zhongwen Xinxi* (Chinese Information Processing), which appeared in 1984 (Fei, 1997).

Applied Linguistics and Minority Languages

The 55 minority ethnic groups occupy a sensitive position within China's officially multicultural state, as their speakers represent some 8% of the population but are located in approximately 64% of the total land area (Dai, Teng, Guan and Dong, 1997: 10). The ten largest minority groups in China are the Zhuangs (16.2 million speakers), the Mans (10.7 million), the Huis (9.8 million), the Miaos (8.9 million), the Uygurs (8.4 million), the Tujias (8.0 million), the Yis (7.8 million), the Mongols (5.8 million), the Zangs or Tibetans (5.4 million), and the Buyeis (3.0 million) (Population Census Office, 2002).

The official language policy toward minorities is inscribed in the section of the Chinese constitution that states that "every ethnic minority is to use and develop their language" (Zhou, 1992: 37). The official educational directive on this issue further states that:

> In schools where the majority of students belong to an ethnic minority, the language of textbooks and instruction should be in the language of that minority, if conditions permit. The Chinese language … should be taught in the last two years of primary school and in middle school to promote the national language. (Article 37 of the Program for the Implementation of Regional Autonomy for Ethnic Minorities, cited and translated in Zhou, 1992: 37.)

In the post-1949 drive to eliminate illiteracy, a number of literacy programs for the minorities have

been organized. Before 1949, excluding the Huis and the Mans who use Chinese, 20 of the 55 minorities already had a written form for their languages; from the 1950s to the 1980s, orthographies were developed for nine other minority groups (Chinese Academy of Social Sciences, 1992; Ministry of Education, People's Republic of China, n.d.). In some regions, the government and schools are now adopting a bilingual language policy aimed at preserving minority languages, yet simultaneously promoting Chinese, although the balance between languages varies greatly from region to region (Zhou, 1992: 38–40).

At present, a particular concern for both Chinese linguists and international concern groups is the plight of a number of endangered languages. Huang (2003) notes that 22 languages in China currently have fewer than ten thousand speakers, and that a process of intergenerational language shift toward Chinese is firmly underway in many regions. Huang (2003: 4) adds that "the minority nationalities lack confidence in their own mother tongues" and believe that "mastery of Chinese will help them secure more opportunities," and he comments that "[t]his has brought the minority nationalities to a crisis with respect to their mother tongues and . . . to lose confidence in the future of their mother tongues". Huang finally reports that since 2002, the Chinese Academy of Social Sciences has been working with the State Commission of Minority Affairs and UNESCO on "programs aimed at rescuing and documenting these endangered languages" (Huang, 2003: 5), but given the powerful economic and political dynamics at work, documentation rather than rescue may have more success.

Perhaps the most direct application of linguistics in relation to minority languages in China has been in the phonological and grammatical descriptions of these languages, a whole series of which have been published by the Central University of Nationalities Press in Beijing. Minority language or minority education issues are explored in journals such as *Minzu Jiaoyu Yanjiu* (*Journal of Research on Education for Ethnic Minorities*), *Minzu Yuwen* (*Ethnic Languages*) and *Guangxi Minzu Yanjiu* (*Studies of Ethnicity in Guangxi*).

Applied Linguistics and Foreign Language Teaching

To understand the role of applied linguistics in foreign language education, it is necessary to also consider the history of China's international relations and foreign policy. In broad terms, one can identify six phases of foreign language education since 1949 (Lam, 2002, 2005) and these are illustrated in Table 1 below.

Russian lessons were first broadcast in Beijing in 1949, and in the early 1950s, in line with its political orientation, China promoted Russian in education. In 1950, Russian departments were established in 19 higher-education colleges, and Russian training courses were organized in several party, government, and military sections. By the following year, these courses had been set up in at least 34 universities and colleges. The emphasis on Russian continued until 1956–1957 when China's foreign policy moved away from the Soviet Union. From that point onward, English replaced Russian as the most important foreign language in China's schools. In 1957, a draft syllabus for teaching English in junior secondary school was distributed, and in 1960, the Beijing Foreign Language School piloted the teaching of English from Primary 3. In 1961, the syllabus for English majors at university level was designed, and in 1962, the first English syllabus for non-English majors in science and technology was published.

The promotion of English at this time might have continued unabated but for the Cultural Revolution, which broke out in 1966 and swept throughout the country. During this period, all academic learning (including foreign language learning) was condemned, although Zhou Enlai, China's Premier from 1949 to 1976, managed to deploy a small number of students to jobs requiring foreign languages. In 1971, in the midst of the Cultural Revolution, China was recognized as a member of the United Nations, and in 1972 Richard Nixon, then President of the United States of America, visited China, establishing a new era of United States–China diplomacy. The biggest breakthrough in foreign language teaching, however, came after the Cultural Revolution, when Deng Xiaoping announced his policy of the Four Modernizations in 1978. In the same year, plans to teach foreign languages from primary school were announced, and the recruitment of foreign teachers to China resumed. Throughout the 1980s, much work was done in drafting or revising syllabi, developing materials and tests, and training teachers at various educational levels, including universities.

To support these developments after 1978, there was an urgent need for educators trained in linguistics, and it was at this time that 'applied linguistics' for foreign language teaching was established as an academic discipline. According to Wang (personal communication, 2003), Guangdong University of Foreign Studies (GUFS) was the very first institution to offer a Master's program in Applied Linguistics in 1978, followed by a Diploma in Applied Linguistics in 1980 and a Doctor of Philosophy in Applied Linguistics in 1986. The first conference on 'Applied Linguistics and English Language Teaching (ELT)'

Table 1 Six phases in foreign language education in China after 1949

Historical period	*Phase in foreign language education*	*Years*
Before the Cultural Revolution	1. The interlude with Russian	Early 1950s
	2. The back-to-English movement	1957–1965
During the Cultural Revolution	3. Repudiation of foreign learning	1966–1970
	4. English for renewing ties with the West	1971–1976
After the Cultural Revolution	5. English for modernization	1977–1990
	6. English for international stature	From 1991

was held at Guangzhou Foreign Language Institute (the predecessor to GUFS) in 1980, with participants from 22 higher-education institutions in China and three institutions from Hong Kong (the University of Hong Kong, the Chinese University of Hong Kong, and the Hong Kong Polytechnic). In the same year, foreign language specialists from China visited the Hong Kong Examinations Authority for advice on test design, and materials development teams in various foreign languages were set up at many universities. In 1984, research projects on various aspects of learning English at university level were conducted. In 1985, an ELT conference at the Guangzhou Foreign Language Institute attracted applied linguists such as Michael Halliday, Henry Widdowson, Peter Strevens, and Alan Maley. Around this time, English specialists from China also began to travel abroad more frequently, and in 1986, the first official delegation from China attended the Teaching English to Speakers of Other Languages (TESOL) conference in Anaheim, California, and presented the 'College English' syllabus for China. In the same year, Fu Ke (1986) published his influential history of foreign language teaching in China (see Sichuan Foreign Language Institute [1993] for a chronology of events in foreign language teaching).

By the early 1990s, applied linguistics had been established as a field of academic activity in China, and a number of Chinese scholars sent overseas for training in the 1970s had returned with new perspectives on foreign language education (Gui, 2002: 2). The disintegration of the Soviet Union in 1991 also provided an opportunity for China to adopt an increasingly international outlook and further expand foreign language education, especially with reference to English. While work on English language curricula at tertiary level continued, attention now turned to English teaching in schools. In May 1990, new guidelines for teaching English in primary school were issued, followed in 1992 by a new syllabus for junior secondary school and, in 1993, for senior secondary school (later revised in 1996). Further international links have also been recently established, and in 2000, the International Association of Teachers of English as a Foreign Language (IATEFL) endorsed the establishment of a China branch. In August 2002, the first IATEFL China conference was held in Tonghua in Jilin province. The year 2002 also saw China joining the International Association of Applied Linguists (AILA) under the aegis of the Chinese English Language Education Association (CELEA).

In China, it is common practice for the government to seek advice from several institutions in different cities to draft syllabi and to develop and pilot materials before they are adopted nationally. In recent decades, key institutions from throughout China have contributed to the national initiatives in the teaching of English and other foreign languages, and thus to 'applied linguistics' in the context of foreign language teaching. Individual institutions have also played an important role in this process, including Guangdong University of Foreign Studies, as mentioned above. GUFS now houses the nationally recognized Center for Linguistics and Applied Linguistics. A key role has also been played by Beijing Foreign Studies University (BFSU) and the Shanghai International Studies University. Beijing Foreign Studies University houses the Foreign Language Teaching and Research Press (FLTRP), the leading publisher of foreign language and applied linguistics materials. The press also sponsors and organizes national conferences on English language teaching in collaboration with the BFSU and the CELEA. Beijing Foreign Studies University is also the home of the National Research Center for Foreign Language Education, which was established at BFSU in March 2000 to conduct research on foreign language education and bilingualism.

Although Chinese 'applied linguistics' in the arena of foreign language teaching did not achieve academic recognition until the late 1970s, it has been professionalizing very rapidly, both through domestic innovations as well as through the education of many linguists overseas. A number of major universities in China now recognize applied linguistics as a distinct academic field. Major journals based in China dealing with foreign language education include *Foreign Language Teaching and Research*, *Modern Foreign Languages*, *Foreign Language Research*, and *Journal of the Foreign Language World* (Gao, Li, and Lu, 2001).

Conclusion

In the sections above, we have attempted to locate our discussion of applied linguistics in China with reference both to the long tradition of Chinese language study and to the recent history of Chinese politics and society. The survey of issues we present in this article indicates that, in recent decades, there have been three broad areas where the influence of applied linguistics (in theory, practice, or both) has been felt: applied linguistics and the Chinese language; applied linguistics and minority languages; and applied linguistics and foreign language education.

With reference to Chinese, initiatives in applied linguistics have focused on the teaching and assessment of *Putonghua* and Standard Chinese to speakers of other dialects and languages and have also involved advances in Chinese information technology. With reference to minority language studies, linguistics has been applied to the description and archiving of such languages, as well as to issues of bilingualism, linguistic description, and language maintenance and loss. At present, applied linguistics in the field of English language teaching displays the greatest international orientation in terms of theory and practice, as might be expected. In the decades ahead there may be increased contacts between these three strands of 'applied' activities as interest in both linguistics and applied linguistics is likely to remain strong in an era of increasing internationalization. Whether that proves to be the case is likely to depend substantially on the degree of institutional support and 'academic space' granted by the educational authorities (in what is still a largely centrally organized educational system) for linguistics, both 'pure' and 'applied.'

Applied Linguistics in Europe

K de Bot, University of Groningen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Applied linguistics is a field with many subdisciplines. The definition of applied linguistics ranges from SLA to language planning, from language ecology to disorders and from mother tongue education to forensic linguistics as the list of AILA scientific commissions witnesses. Grabe (2002: 10) defines applied linguistics (AL) as "... [A] practice driven discipline that addresses language based problems in real-world contexts." Although the use of such a limiting definition would make it somewhat easier to select topics, the 'practice-driven' focus would force us to leave out some of the fundamental research carried out in the European context. What is presented is for the major part typically European, which is not to say that the themes and paradigm are not of interest and studied in other parts of the world. Given the large amount of applied linguistic research in the European setting, it is impossible to cover everything within one article.

One limitation should be mentioned here: The research discussed is basically mainland European. Applied linguistics in Great Britain and Ireland has a long history and a very active present, and it would be impossible to include the specific issues from that context into the larger European picture.

Applied linguistic research has been carried out on a wide range of topics. In order to give some structure to this overview, the research is presented under the following headings:

- Language planning and policy
- Sociolinguistic aspects of multilingualism
- Psycholinguistic aspects of multilingualism

Language Planning and Policy

The end of World War II also meant the beginning of the Cold War and the division of Europe into two zones of influence: the western part that organized itself strategically in NATO and the eastern part that became dominated by the USSR and Warsaw Pact. Linguistically this meant that these two zones came under different influences: although in the western part English and, to a lesser extent, French dominated the scene, in the eastern part Russian became the language of wider communication and the language taught widely in education. German continued to play an important role in Eastern Europe, in particular in academia, whereas its role was very limited in Western Europe. Rannut and Rannut (1995) discuss the specific problems of setting up a language policy in Estonia after the Soviet era. Estonia is faced with the difficult task of strengthening the position of the Estonian language, while at the same time taking into account the needs of the monolingual Russian speakers in Estonia. As Leontiev (1995) mentions, similar problems occur in the autonomous republics of the former USSR to where large numbers of Russians migrated, often driven by force. They now face problems in the republics in which they have been living for a long time: "Because of their monolingualism, they are excluded from the cultural life of the state. They cannot understand the media or official documents, unless Russian is the second official language

Applied linguistics is a field with many subdisciplines. The definition of applied linguistics ranges from SLA to language planning, from language ecology to disorders and from mother tongue education to forensic linguistics as the list of AILA scientific commissions witnesses. Grabe (2002: 10) defines applied linguistics (AL) as "... [A] practice driven discipline that addresses language based problems in real-world contexts." Although the use of such a limiting definition would make it somewhat easier to select topics, the 'practice-driven' focus would force us to leave out some of the fundamental research carried out in the European context. What is presented is for the major part typically European, which is not to say that the themes and paradigm are not of interest and studied in other parts of the world. Given the large amount of applied linguistic research in the European setting, it is impossible to cover everything within one article.

One limitation should be mentioned here: The research discussed is basically mainland European. Applied linguistics in Great Britain and Ireland has a long history and a very active present, and it would be impossible to include the specific issues from that context into the larger European picture.

Applied linguistic research has been carried out on a wide range of topics. In order to give some structure to this overview, the research is presented under the following headings:

- Language planning and policy
- Sociolinguistic aspects of multilingualism
- Psycholinguistic aspects of multilingualism

Language Planning and Policy

The end of World War II also meant the beginning of the Cold War and the division of Europe into two zones of influence: the western part that organized itself strategically in NATO and the eastern part that became dominated by the USSR and Warsaw Pact. Linguistically this meant that these two zones came under different influences: although in the western part English and, to a lesser extent, French dominated the scene, in the eastern part Russian became the language of wider communication and the language taught widely in education. German continued to play an important role in Eastern Europe, in particular in academia, whereas its role was very limited in Western Europe. Rannut and Rannut (1995) discuss the specific problems of setting up a language policy in Estonia after the Soviet era. Estonia is faced with the difficult task of strengthening the position of the Estonian language, while at the same time taking into account the needs of the monolingual Russian speakers in Estonia. As Leontiev (1995) mentions, similar problems occur in the autonomous republics of the former USSR to where large numbers of Russians migrated, often driven by force. They now face problems in the republics in which they have been living for a long time: "Because of their monolingualism, they are excluded from the cultural life of the state. They cannot understand the media or official documents, unless Russian is the second official language

of the new state. Many of them do not want to learn a 'new' language: They have no real experience of being bilingual or multilingual, as for instance citizens of Switzerland have" (Leontiev, 1995: 199–200).

Language in the European Union

In multilingual Europe, linguistic differences have always played a role. Languages typically were regarded as the core of national identity and therefore they were and are highly symbolic of developments in Europe. In this respect, it is interesting that is was a French politician, Jean Monnet, who became the main actor in the development of several associations between western European countries that led to the emergence of the European Economic Community (EEC) and later the European Union (EU), which has recently grown from 15 members to 25 members. The impact of the development of the EU on almost all aspects of language and language policy can hardly be overestimated. Here we will focus on a number of developments that are directly or indirectly related to the emergence of the EU and discuss some of the research that has been done in relation to this.

A number of issues have to be discussed here:

- Language policies in the EU
  - Content and language integrated learning
  - An early start for foreign languages
  - The development of the European common Framework of Reference
- The choice of languages in the EU.

The main aim of the EU is the formation of a united Europe with open borders and active communication between residents. To achieve this, various policy measures have been enacted, in particular with respect to learning foreign languages. In a 1998 meeting of the EU ministers of education, a long list of intentions was presented aimed at the development of multilingualism in the EU. These intentions aimed to enable "all Europeans to communicate with speakers of other mother tongues, thereby developing open-mindedness, facilitating free movement of people and exchange of information and improving international cooperation" (Recommendation R (98) 6 of the European Council). Among the recommendations listed are the learning of more than one foreign language by all citizens, the use of foreign languages in the teaching of nonlinguistic subjects (for example, history or mathematics), an early start for the teaching of foreign languages, the promotion of lifelong learning of foreign languages, and a focus on learner autonomy. Although the last point has not attracted much attention in the European research community, there has been more research undertaken on various forms of content-based instruction, or what in the European context has become known as CLIL: Content and Language Integrated Learning (Marsh, 2002). In many European countries, this form of language teaching has become popular, although it also should be mentioned that in the vast majorities of schools the foreign language taught is English and only a few schools offer CLIL with any of the other EU languages.

An Early Start for Foreign Languages

In the literature on early bilingualism there are numerous studies on children who have been brought up in two languages. There is a long European tradition that began with the seminal work of Ronjat (1913) on his son Louis, who was brought up in French and German, and Leopold (1939–1949), who made careful analyses of his daughter Hildegardt's development in German and English. More recent work on simultaneous bilingualism includes work by Arnberg (1987), De Houwer (1990), Meisel (1990), and Lanza (1997). One of the main research questions is when and to what extent young children develop separate systems for their different languages and to what extent the well-known principle of one parent–one language is really necessary for full bilingual development.

There is much less research on early consecutive bilingualism (Kielhöfer and Jonekeit, 1983), but there is growing interest in the development of bilingualism through early bilingual schooling that is becoming more popular because of the EU's policy to promote an early start for foreign language learning (Leman, 1991; Housen and Baetens Beardsmore, 1993). In policy documents on early foreign language teaching, the distinction between early simultaneous acquisition and early language teaching in schools is not always made, and some of the findings showing high levels of proficiency in children that have been brought up bilingually are too easily used to claim equally positive outcomes for foreign language teaching in primary education.

The Common European Framework of Reference (CEFR)

One of the problems in defining a language policy with respect to the teaching and learning of languages in the EU was how to define levels of proficiency in a foreign language. The need for a common framework of reference became one of the spearheads of language policy in Europe. North and Schneider (1998) report on a large project set up to compare systems of reference for various national and commercial language tests and examinations and present a system that is primarily based on self-evaluation

through the use of so-called can-do statements ("I am able to understand a conversation between native speakers when they speak at a normal speed about non-specialist topics": 1 = not at all . . . 5 = without problems). The resulting Common European Framework of Reference (CEFR; Council of Europe, 1996) has become the standard for both national examinations and commercial placement tests, such as the Cambridge Exams for English. Although the use of the can-do scales is not without problems, they have now become the standard in research that aims at comparing foreign language proficiency between countries (see, for instance, the evaluation of English proficiency at the end of compulsory education in different countries reported on by Bonnet, 2004).

The Choice of Languages in the EU

Inevitably, questions arose following the establishment of the EEC and the EU based on various aspects of the emergence of language as a political issue: What should the language or languages of the EU be; How many languages should inhabitants of member states be able to speak; How can we test language proficiency over countries through a unified system?

In the EU in its pre-May 2004 form there were 13 official national languages, ranging from German with 63 million speakers to Letzebuergesh with 0.4 million speakers. In addition, there were several so-called autochthonous languages, ranging from Catalan with 10 million speakers to Gaelic with 0.1 million speakers (Ammon *et al*., 1991). Of the national languages, 11 languages were official and working languages for the EU. For the running of the EU as an organization, this large number of working languages has become a heavy financial burden, because all documents have to be made available in all working languages; in all meetings, all languages can be used, and so there has to be simultaneous interpreting for all possible language combinations. With the enlargement of the EU this problem will become even more pressing, not only because the number of languages and, accordingly, the number of possible combinations will grow dramatically but also because it will be very difficult to find sufficient numbers of translators and interpreters for all language combinations. Van Els (2004), in his analysis of the use of languages in the EU and its institutions, considers various models to simplify the language regime in the EU. The language issue is a very sensitive one, because giving up a language as one of the official languages is seen as a serious devaluation of and threat to the position of a language nationally and internationally. Defendants of national languages urge their representatives in all committees and working groups to insist on the presence of interpreters, whereas in the daily running of the EU at the lower levels the general practice is that only English and French are used. Van Els discusses various options, which broadly fall into two groups: restrictive (not all languages as working languages) and nonrestrictive (all languages allowed). He rejects the financial argument related to the costs of translation and interpreting, observing that the EU falling apart because of the language issue would be far more costly. For the restrictive options he mentions various choices, such as a smaller number of languages (German, French, English), the use of an international language (Esperanto), and English only. Van Els concludes that in the end the last choice, only English, is the only feasible one, if not because it causes less damage than any of the other options, then because no politician will be brave enough to really try to solve the issue, and doing nothing means that in practice English becomes the working language in most meetings. The use of the other languages will become more or less symbolic.

Sociolinguistic Aspects of Multilingualism

The Position of English and Other Languages in Europe

It is one of those curious developments in European history that English has become the dominant language in Europe although its country of origin has played a marginal political role on the European scene. For quite some time, Great Britain was not accepted as a member of the EU. At first, then French president Charles the Gaulle opposed the entry of Great Britain, fearing it would weaken the German–French axis; later, entry was opposed because Great Britain did not meet the economic criteria for new members. As a consequence, the English language was never actively promoted by the British, or at any rate not nearly as much as French was defended by the French government, which wanted to maintain French as the language of diplomacy (Willingham-McLain, 1997).

With the extension of the EU (an addition of 13 new member states), the linguistic scene is changing dramatically. Holdworth (2003) mentions statistics on foreign language skills that show that the majority of the people in the new member states are bilingual or multilingual and that in those countries Russian is the most widely spoken foreign language, followed by German. If we look at language skills in the enlarged EU as compared to the present situation an interesting picture emerges. Table 1 contains the percentages of

Table 1 Percentages of inhabitants of EU with basic knowledge of a foreign language

	EU of 15 states	*EU of 28 states*
English	40%	35%
German	18%	16%
Russian	>1%	11%
French	16%	10%

people that claim that they can hold a conversation in that foreign language.

These figures show that the position of English and German – and, in particular, French – is weakened. The Russian language still holds a strong position, but it is not clear whether that will last, because the call for English in the new states on all levels of society will inevitably grow at the expense of Russian.

Graddol (2004) presents data on proficiency in English in the present EU showing that in Denmark, Sweden, and the Netherlands more than 75% of the people interviewed claim to be able to hold a conversation in English. In Luxembourg, Finland, Belgium, Germany, and Greece, 40 to 50% can hold a conversation in English, whereas fewer than 30% can do so in Italy, Portugal, and Spain. These figures show that the knowledge of English may not be as widespread as is sometimes assumed, and that its dominant position might not be as overwhelming as previously thought. As Graddol (2004, 1330) puts it:

> Any look into the future must entertain the idea that soon the entire world will speak English. Many believe English will become the world language to the exclusion of all others. But this idea, which first took root in the 19th century, is past its sell-by date. English will indeed play a crucial role in shaping the new world linguistic order, but its major impact will be in creating new generations of bilingual and multilingual speakers across the world.

From Bilingualism to Multilingualism

A typical European issue is the growing interest in trilingualism and multilingualism. In German-speaking countries in particular, the interest in what is basically 'English plus x' has led to a range of projects on trilingualism from both a theoretical perspective (Dewaele, 1998; Jessner, 2000) and a language teaching perspective (Dentler *et al*., 2000). One of the most important outcomes of this research is that, in multilingualism, all language systems interact: The mother tongue can affect and also be affected by the second or third language. In some bilingual regions in Europe, such as the Basque country and the Province of Friesland in the Netherlands, English is taught as a third language.

Sociolinguistic Aspects of Multilingualism

SLA and Migration

The booming of the economy in Western Europe that first came about as a result of American support for the rebuilding of Europe (under the Marshall Plan) and later on the development of trade and agriculture led to the rapid growth of labor migration from countries in southern Europe, North Africa, and Turkey to Germany, France, the Low Countries, and the Nordic Countries. This migration quickly turned from temporary stay into permanent residence and family formation in the immigrant countries. This led to a number of language-related problems. Because of low proficiency in the language of the immigrant country, many migrant workers never integrated; in particular, their children suffered from low educational achievements, and accordingly there were higher risks of educational dropout and unemployment. In many countries, initiatives were taken to improve language skills of the migrants and their children and a number of large-scale projects were set up to study the language development of those groups. Probably the best-known example was the ESF project, "Second Language Acquisition by Adult Immigrants," coordinated by Wolfgang Klein and Clive Perdue in 1992. In the project, the acquisition of different languages by speakers with different L1s was studied in a then well-known "saw-tooth" pattern:

English German Dutch French Swedish
Punjabi Italian Turkish Arabic Spanish Finnish

So, for example, the acquisition of German by Italian and Turkish learners was compared to the learning of English by Italian learners and Dutch by Turkish learners, enabling a cross-linguistic comparison between both source and target language. One of the outcomes of this research was the development of what became known as 'the basic variety': "One of our findings is that all our learners, irrespective of the source and target language, develop a particular way of structuring their utterances which seems to present a natural equilibrium between the various phrasal, semantic and pragmatic constraints" (Klein and Perdue, 1992: 311).

Languages in Contact

There are many national languages, minority languages, regiolects, and dialects in Europe, and therefore language contact is a common phenomenon. There is also a long-standing interest in this. Weinreich's well-known *Languages in contact* (1953) is an early example of research that takes into account linguistic, sociolinguistic, and – to a certain extent – even psycholinguistic

aspects of language contact. There are few examples of language contact situations in which the two languages live in peace alongside each other. In most cases, there is a difference in status and this implies that the weaker language is in danger to being overtaken by the stronger one. Nelde (1987) aptly described this: Language contact is language conflict. As we will see later, in the discussion on maintenance and loss of minority languages, this is the reality for many languages, and, as some argue, even all languages except English.

At the same time, we see the development of new varieties resulting from language contact, along the lines of Graddoll (2004). In Germany, in particular, there is a growing group of researchers who are interested in the contact languages that develop in multiethnic cities. For some, those new varieties pose serious threats for young people with a migrant background, because the kind of input they need for their education and their position on the job market is limited when they only speak these youth varieties. Schlobinski *et al.* (1993: 9) cites several very negative comments on such youth language, but not all comments have this sombre tone. For many linguists, the development of such 'wild' varieties is a sign of the ability of languages to renew themselves and to adapt to new situations. Youth language often has a sort of 'secret language' function aimed at the exclusion of outsiders in the communication and it clearly reflects the interests of the age group of 12- to 18-year-olds. Varieties are typically unstable, and being able to joggle with the language and be creative with new words adds prestige.

Maintenance and Loss of Minority Languages

Because of the changes taking place in Europe, two trends in language contact have emerged: the migration to Western Europe by various groups from Southern Europe, North Africa, and Turkey, and the growing impact of national languages on nonmigrant minorities. Both trends have been investigated in terms of the maintenance and loss of minority languages in various parts of Europe. The loss of language skills in migrant languages has been studied in many European countries. Fase *et al.* (1995) and Ammerlaan *et al.* (2001) present many examples of this line of research.

Regionalization

The tendency of larger and more powerful languages to dominate the smaller ones has led to a strong reaction in various countries to support and strengthen the position of smaller languages. Within the EU, several resolutions have been adopted aimed at protecting regional minority languages. These actions have led to the foundation of the European Bureau for Lesser Used Languages (EBLUL) and a very active MERCATOR network in which representatives from most regional minority languages cooperate. The European Charter for Regional or Minority Languages (1992) was a milestone, because all member states that ratified the Charter had to take positive action to protect and support their regional minority languages. This clearly strengthened the position of those languages, although there are important differences between the various regions.

The almost comfortable position of regional languages in Europe stands in sharp contrast with the weak position of migrant languages in those countries. In that sense, there is an uneasy relation between proponents of migrant languages and other minority languages in Europe. Extra (1989) points to the fact that the arrangements for local or regional minority languages (such as Frisian and Basque) are generally much more supportive for language maintenance than the arrangements for migrant languages. In more recent publications, the defenders of the rights of the two minority communities – regional and migrant – seem to have found a common interest in campaigning for the rights of minority languages. In an aptly titled edited volume, *The other languages of Europe*, Extra and Gorter (2001) argue for the provision of teaching for both migrant and regional minority languages.

Psycholinguistic Aspects of Multilingualism

Although the interest in psycholinguistic aspects of multilingualism is not a typically European topic, it certainly is a field in which European researchers have been key players. The focus has been on the lexicon as well as on the role of cognitive processing in language acquisition and use. The central question most of the research is concerned with is language specific versus nonspecific access. In other words, when we are confronted with a word, e.g., in a lexical decision task, do we first access the lexicon from one language and then the next, or is there a parallel search through all languages, with words not being organized primarily through language, but, e.g., through frequency. In the past, the language selective position was favored but in the last two decades research has accumulated to support the nonselective view. A number of experimental paradigms have been used to study this question, these include various forms of lexical decision with or without priming (Dijkstra and van Heuven, 1998), translation (de Groot *et al.*, 2000) and word naming (Hermans *et al.*, 1998). Overall, the evidence in support of the nonselective access hypothesis is

substantial, and much stronger than for the selective access hypothesis.

There is a large body of research on psycholinguistic aspects of language acquisition and language attrition. Again, even a global overview of that research would take more space than is available here. There is a strong tradition in various European countries to apply the Chomskian generative framework to second language acquisition. More functionally or cognitive linguistically oriented studies also have been carried out. The ESF project mentioned earlier falls within this category. A direct link between cognitive processing and SLA is made in work by Hulstijn (e.g., Hulstijn, 2002) and Pienemann (1998). Their main claim is that language acquisition is constrained not so much by the linguistic characteristics of the language but, rather, by the cognitive processing mechanisms. Good overviews of the study of linguistic aspects in SLA can be found in the EUROSLA yearbooks that contain articles based on the annual EUROSLA conferences.

Language Attrition

One specific line of research that has a firm European basis is the study of language attrition, i.e., the decline of language skills in individuals over time. Research on attrition has proven to be relevant, both from a language policy perspective ('Why teach a language if you forget it quickly?') and from a psycholinguistic perspective ('How is knowledge stored and lost?'). Research on this topic has been carried out over the last 20 years in several European countries (see Weltens *et al*., 1986, for an account of early studies, and Schmidt and Köpke, 2004, for more recent ones). There is also some research using more advanced neuro-imaging techniques to study language attrition: Pallier *et al*. (2003) used such techniques to study the attrition of the first language among adopted Korean children living in France.

Final Remarks

In this article, an attempt has been made to provide a sketch of what has been going on in applied linguistics in Europe. The focus has been on the relationship 'between language in use and the complex sociolinguistic situation in Europe rather than the specific contributions to applied linguistics made by European researchers.

What might be the direction of future developments for applied linguistics in Europe? A number of issues are likely to gain further prominence in the near future. These include the following:

- Further expansion of EU: What other languages, how many, what are the costs?
- Growth of English at the expense of other languages in all walks of life, and the detrimental effect this will have on the learning of other foreign languages.
- Language and aging in migrants: The first wave of migrants is now reaching old age, and with that come problems related to physical and cognitive decline. Few countries are ready to take appropriate measures to deal with this problem.
- The role of national language/local language/ English: One scenario is that English will become the language of wider communication for all Europeans, but that Europeans will stick to their local language as the language of comfort and solidarity. This may mean that the role of national languages is undermined, because there will be no role for them to play.
- The future of foreign language teaching: Will there still be foreign language learning and teaching other than English?
- Neuro-imaging studies of second language use, learning, and forgetting: These new techniques offer very interesting opportunities to get to the basics of multilingual processing.

Applied Linguistics in North America

W Grabe, Northern Arizona University, Flagstaff, AZ, USA
R B Kaplan, Port Angeles, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

Applied linguistics has been, and continues to be, a very active academic field in North America. Over the past 30 years, applied linguistics has gained steady recognition as an academic discipline. There are more than 45 academic departments and programs in applied linguistics at North American universities, and applied linguists work in English departments, modern languages departments, education departments, linguistics departments, and communications departments. There are more than 20 national and international academic journals in applied linguistics with major contributions by North American researchers. The American Association for Applied Linguistics (AAAL) has 1500 members, and its annual meeting regularly attracts approximately 1000 participants. Large groups of applied linguists are also in regular attendance at the meetings of the Modern Language Association (MLA), Teachers of English to Speakers of Other Languages, Inc. (TESOL), and the American Council of Teachers of Foreign languages (ACTFL). Moreover, applied linguists dominate the Second Language Research Forum (SLRF) and the Language Testing Research Colloquium (LTRC) at their annual meetings. Conservatively, there are a few thousand applied linguists in North America, not counting the many thousands of second and foreign language teachers.

The AAAL is the leading organization for applied linguists in North America with strong executive board representation from both Canada and the United States. AAAL provides one fairly objective way to interpret the nature and scope of applied linguistics in North America through the categories established in their annual call for paper abstracts. This listing of categories defines the broad, inclusive nature of the field without making very strong claims to represent allied disciplines (e.g., English, rhetoric, education, communications, speech pathology). We provide a 3-year synthesis of this 'call for papers,' adjusting the list for slight variations in subfield labels that arise from year to year. It is important to recognize that these categories, for the most part, apply to second-language contexts, though many issues of language policy, language socialization, discourse analysis, and dialect variation incorporate both second and foreign language (L2) and first language (L1) situations.

1. Assessment & Evaluation
2. Bilingual, Immersion, Heritage, Minority Language Learners
3. Critical Linguistics & Language Ideology
4. Discourse Analysis
5. Language Acquisition & Attrition
6. Language, Cognition, & the Brain
7. Language, Culture, & Socialization
8. Language Policy & Planning
9. Reading, Writing, & Literacy
10. Research Methods & Applied Linguistics
11. Second & Foreign Language Pedagogy
12. Sociolinguistics
13. Technology & Language
14. Translation & Interpretation

There are, in fact, several other ways to define and interpret the field of applied linguistics. We will briefly note this debate as a way to establish the rationale for the research that we review under various categories below.

A Brief History of Applied Linguistics in North America

There have been several discussions on the origins of applied linguistics. From a North American perspective, the first use of the term dates back to the English Language Institute at the University of Michigan in the 1940s. A group of professors and language teachers wanted to be identified with scientific concepts, rather than more casual humanistic and educational approaches to language learning. From this beginning also emerged the journal *Language Learning: A Journal of Applied Linguistics* in 1948.

In the 1950s and 1960s, applied linguistics expanded considerably, along with the great increase in the number of foreign students going to North American universities to study. In the mid-1950s, the Ford Foundation, based in New York, became heavily involved in establishing centers for applied linguistics in various parts of the world including Hyderabad, Cairo, Tunis, the West Indies, and Washington, D.C. The Center for Applied Linguistics in Washington, D.C. opened in 1959. In the 1960s, the professional teacher organization, TESOL, was formed and had its first annual conference in 1966. In 1967, *TESOL Quarterly* began publication, providing a second North American-based applied linguistics journal. By 1969, TESOL began to develop interest sections. The Applied Linguistics Interest Section constituted the primary (and for a time, the sole) venue for applied linguistics activity and research in the United States.

In the 1970s and 1980s, applied linguistics underwent a maturing process in North America. The first Ph.D. program specifically in applied linguistics was offered at the University of California, Los Angeles (UCLA) in 1977, with other programs following fairly quickly. The AAAL was formed in 1977. The late 1970s and early 1980s were also a time in which many new journals appeared to support and energize the growing field, including *Applied Linguistics*, *Annual Review of Applied Linguistics*, and *The ESP Journal*. By the 1980s, the field began a series of discussions that continues even to the present, concerning the nature and status of applied linguistics (Kaplan, 1980, 2002).

Defining and Delimiting Applied Linguistics

Over the past five years, there have been a number of publications that have explored the nature and status of applied linguistics, with both North American and European emphases (Candlin and Sarangi, 2004; Davies and Elder, 2004; Kaplan, 2002; Widdowson, 2003). There is no longer serious debate about the larger interdisciplinary scope of applied linguistics, as opposed to an earlier and more limited interpretation as a designation for language teachers, language-teacher trainers, and language testers. To be sure, the fields of language learning, language teaching, and language testing are still central components in applied linguistics, but the disciplinary discussions of the 1980s and 1990s have established applied linguistics as an interdisciplinary field that addresses real-world language problems of various types.

Applied linguistics is a field that centrally involves linguistic knowledge and training. That knowledge is combined with one or two other specialized concerns and is applied to problems that arise in the normal (and sometimes abnormal) course of daily life. These problems include needing to learn and use a second or third language; being taught in an L2 in an effective manner; being assessed and evaluated in an L2; negotiating services or health care in an L2; being impacted by language policies (whether planned or unplanned) that apply in educational, institutional, civic, or work settings; needing interpreter services for various reasons; and maintaining home languages in dominant L2 contexts. These problems, and several others like them, are the core of the field of applied linguistics.

Seeing the field from the perspective of language problems makes clear the fact that no one academic discipline is going to serve the needs of people facing such problems. No person trained in education or psychology will be able to work effectively with language problems if he or she does not also have a strong grounding in linguistic knowledge. Conversely, a linguist who is not also grounded in some other relevant discipline will not be able to approach language-based problems effectively. For example, a linguist with little education/pedagogical background will not be able to address major language-learning and language-teaching issues. To solve real-world language issues requires expert knowledge across specific disciplines; for this reason, 'linguistics applied' can never be an adequate substitution for applied linguistics.

Applied linguistics, in the broader context, encompasses second language learning and teaching, language assessment, language policy and planning, language use (and misuse) in professional and occupational settings, language contact and bi/multilingualism, and translation. It is also a major contributor to research in literacy, corpus linguistics, lexicography, teacher training, and sociolinguistics. Somewhat more distantly, it has linkages to allied disciplines such as education, cognitive psychology, English studies (stylistics, rhetoric, discourse studies, and literary studies), foreign languages (discourse, culture, and literary studies), speech pathology, and communications.

The goal of representing applied linguistics in these wider terms is to establish the taxonomy of applied linguistics research that we review in the following sections. Taking a broad view not only reflects the current nature of applied linguistics, at least as understood in North America, but also ensures that the work of applied linguistics from various backgrounds is reasonably represented in our overview. In covering research work over the past six to eight years, we will use the classification given below.

1. Second language acquisition
2. L2 reading and writing research
3. Language learning and teaching
   a. Second language teaching (English for Academic Purposes)
   b. Foreign language teaching
   c. Bilingual and language minority education
   d. Instructional approaches
4. Language assessment
5. Language policy and planning
6. Societal bilingualism and language contact
7. Language use in professional contexts
8. Corpus linguistics

These categories represent the core of applied linguistics and will be the focus of the remaining discussion.

Many of these subfields are large and complex. We will provide only some insights into the work being done in these areas.

Research in Applied Linguistics in North America

Second Language Acquisition

The greatest amount of applied linguistics research in North America is done in the area of second language acquisition (SLA). Detailed coverage of this work was well represented in the recent *Handbook of second language acquisition* (Doughty and Long, 2003). There are many subfields within SLA, and there is no agreed-upon taxonomy of areas within SLA. We have organized our comments on subfields in a way that is reasonable, but we make no claims to a definitive taxonomy. We will offer only a few comments on SLA since it is already well covered elsewhere in this encyclopedia.

Cognitive SLA, as a general cover term, is by far the largest grouping within SLA. It includes all areas that see second language learning as an individual developmental process, and it explores various alternative views on how learning occurs, in both the short- and long-term. One way to divide the territory is to distinguish functional (or descriptive) linguistic orientations from formal linguistic orientations; a second way is to distinguish representational orientations from processing orientations in research.

Functional linguistic orientations include the roles of input and output in learning, of attention and awareness, of negotiated interaction, of 'Focus-on-Form' as opposed to focus on forms (standard grammar instruction), of strategies, of motivation and affective responses, of individual differences in cognitive learning traits. It also focuses on the importance of transfer in learning, the impact of the critical period hypothesis and the limits of ultimate attainment for learning (Doughty and Long, 2003; VanPatten, 2003). More formal linguistic orientations include the role of hypothesized categories and constraints on performance, the status of the initial linguistic state on learning outcomes, and the impact of specific underlying structures on learning outcomes (White, 2004).

Other subfields that have gained in prominence over the years include: sociolinguistic, sociocultural, pragmatic, social-psychological, and neurolinguistic orientations. Sociolinguistic orientations cover learner-language variability, as well as variability in the linguistic input and the influence of cross-cultural factors on language use and communication. Sociocultural factors draw heavily on Vygotskian explanations for cognitive development, examine how social interactions trigger learning, and how peers and more knowledgeable partners in interaction provide the input and support for the transfer of learning. Pragmatic perspectives focus on the role of pragmatics in language learning, pragmatic cross-cultural miscommunication, and the nature of pragmatic transfer. Social-psychological views of SLA provide a hybrid perspective on SLA, focusing on how social factors impact psychological performance and, in this case, second language learning. In the North American setting, research focuses specifically on the relation between integrative motivation and language learning, the role of instrumental motivation, and the range of wider social factors that influence language learning. Neurolinguistic explorations in SLA are just beginning, but the potential is considerable. To date, most neurolinguistic work in SLA has examined the role of motivation and affect on learning performance (Schumann *et al.*, 2004). All of the subfields noted in this section could be the source for entire books (see Grabe, 2004 for more detailed overview).

L2 Reading and Writing Research

In any general understanding of language learning, one might consider research on reading and writing development to be part of SLA. However, this subfield is treated separately in this article because reading and writing are not seen as important aspects of SLA in North America; most books on SLA do not discuss reading, writing, or literacy development. While this is somewhat odd, given the many articles related to reading and writing in journals oriented to second language learning, it is, nonetheless, the case that much of the theorizing about SLA does not specifically take into account the learning of reading or writing abilities. For this reason, we comment on L2 reading and writing development separately.

A considerable amount of research in L2 reading has been carried out on specific processes involved in reading, including word recognition, morphological processing, and sentence processing. Research over the past decade has shown that all of these processing factors strongly influence reading abilities. A second area of importance for L2 reading is the role of language transfer, demonstrating that phonological processing, morphological awareness, and reading strategies are capable of transfer, though at differing times in the development of L2 reading abilities. Other research has focused on metalinguistic knowledge, metacognition, and reading strategies, arguing that metacognitive and metalinguistic awareness play

important roles in reading development (Cohen, 1998; Koda, 2005).

Writing research in L2 contexts is an area in which an extensive amount of research is done, much of which focuses on university and pre-university student writers. Several overview volumes on writing research cover a wide range of issues, including the role of feedback and responding to L2 writers, genre influences on writing, research in contrastive rhetoric and its criticisms, the use of corpus analysis to study L2 writing, and L2 writing assessment (Ferris and Hedgcock, 2004; Kroll, 2003).

Language Learning and Teaching

The category of language learning and teaching focuses more generally on the classroom contexts in which language are taught. Under this heading, North American scholars focus on second language teaching (with a very large emphasis on English for Academic Purposes), foreign language teaching, bilingual education and language minority education, and a range of instructional approaches that take on the status and purpose of curricular approaches for teaching.

Second Language Teaching (and English for Academic Purposes) Much like research on L2 reading and writing, there is a strong emphasis in research and scholarly articles focusing on second language teaching with university and pre-university students. In the United States, some of the most popular methodology texts by North American authors address the adolescent or adult learners. Celce-Murcia (2001) provides coverage for K–12 student contexts, but the majority of the book is aimed at older students and students learning English for academic purposes. K–12 research and resource texts are regularly produced by the Center for Applied Linguistics. In Canada, the ongoing work of language immersion programs has led to much greater study of L2 learning in K–12 contexts (Swain, 2000).

Foreign Language Teaching In North America, foreign language teaching has a lesser, but still important, role to play in student education. Unlike other regions of the world, where all students are exposed to one or more foreign languages for long periods in the educational curriculum, foreign language learning is not required at all in some secondary schools; most secondary school students have three years of one foreign language. In university settings, foreign language requirements are decreasing. In Canada, with its federal bilingual policy and 20-year history of language immersion programs, there is somewhat more emphasis on learning another language. Nonetheless, there are still a large number of students learning a foreign language in both the United States and Canada. Enrollments in foreign language courses in the United States are at about the same level in 2000 as they were in 1970 (approximately 1.1 million students in university courses). Aside from Spanish, however, many traditional foreign languages are in decline (e.g., French, German, Russian), and the number of university majors in recent years has declined by one-third (Klee, 2000).

Bilingual and Language Minority Education Bilingual education in both Canada and the United States is an issue that has led to much discussion and debate. In Canada, bilingual instruction, whether as immersion or as heritage language instruction, has been more widely accepted than in the United States. Much research on bilingual instruction and second language learning has emerged in this context. In the United States, where governmental and community groups are usually less supportive, bilingual education is on the defensive. One might expect more support for bilingual and foreign language instruction in a country where approximately 18% of the population speaks a language other than English in the home. However, social and political issues drive the discussion in the United States more than do educational issues (Crawford, 2003). A large part of the discussion on bilingual education in the United States is the debate over its effectiveness on student learning. Cummins (2000) and Valdez (2001) both provided an important overview of this issue.

Instructional Approaches Second language instruction at more advanced levels or with older students usually involves either communicative language teaching approaches or more traditional language skills approaches (see McGroarty, 2004). In non-academic and adult education contexts, communicative language teaching (CLT) dominates L2 instruction. Language skills instruction, in contrast, is more prevalent in academic-purposes settings. In K–12 settings, there is also an emphasis on whole language instruction (reading authentic texts, reading extensively, no reading-skills instruction, extended writing) in many L2 classes. Over the past 10 years, there has been greater emphasis placed on learning strategy instruction, task-based instruction (TBI), and content-based instruction (CBI). These last two curricular approaches have gained popularity in North America. TBI is an easily adaptable approach for CLT curricula, and it is a preferred orientation for much SLA research. CBI introduces students to specific content material, and through learning the material, language is learned as a result. CBI draws

heavily for thematic ideas on both L1 elementary instruction and also on EAP courses in academic settings. TBI and CBI are not conflicting curricular options, but complementary ones. Both focus on meaning and conveying information; both focus on language learning indirectly as part of learning and using other information; and both have the potential to engage learners in meaningful project work.

Language Assessment

Language assessment research has been an important part of applied linguistics over the past 20 years. Several testing issues have generated much discussion over the past decade: test validity, fairness in testing, performance assessment, evidence-centered design, language-skills constructs, and technology in language assessment. Validity in language assessment gained prominence as a driving concept for language test design and use (Bachman and Palmer, 1996). Validity discussions have generated much debate over fairness in testing and ethical testing practices.

Performance assessment has been the source of much discussion (drawing on workplace performance assessment and professional licensing examinations). Performance assessment ties in closely with TBI and the need to demonstrate successful outcomes on various language tasks. Another development in language testing in the past decade has been the movement for evidence-centered design in language assessment. This approach focuses on the evidence linking the tasks used in assessment to the constructs to be assessed and the inferences made from scores given. Two further developments have been the return to language-skills assessments and the increasing use of technology in assessment. Evidence for both of these trends was seen in the assessment volumes appearing in the past five years as the Cambridge University Press assessment series (e.g., Douglas, 2000; Read, 2000; series editors, Lyle Bachman and Charles Alderson), and in the research supporting the design of New TOEFL (TOEFL Research Monographs series, 28 volumes to date, Educational Testing Service: 1995–2004).

Language Policy and Planning

Language policy and planning has been another important part of applied linguistics in North America. Included among key issues are the debates around bilingual education, the English-only movement, government language policies in Canada, and the development of models for engaging in language policy and planning activities. Canada has formal language policies and an official bilingual policy at the federal level, and the federal and regional governments provide some support for minority and heritage languages.

The United States does not have a clearly articulated language policy, and many language policy debates are not worked out through rational and planned discussions. The Ebonics debate is a good case in point. The emotional arguments over African-American dialect use in school arose in the public media, and many competing, if ill-informed, perspectives prevented any rational discussion or effective policy development from being carried out. Similarly, many versions of English-only amendments are adopted by states based on emotional and racist arguments. These examples illustrate the many unforeseen consequences of political and adversarial language policies (or perhaps, nonpolicies; see chapters in Finegan and Rickford, 2004; see Kaplan and Baldauf, 1997 for general overview).

Societal Bilingualism and Language Contact

Bilingualism and language contact situations most commonly lead to analyses of new dialect formation, as well as examinations of language spread, maintenance, shift, and death. The spread of English in North America (and elsewhere) and the growth of immigrant populations in the United States and Canada have led to analyses and overviews on language contact situations in both countries (see Finegan and Rickford, 2004). In North American contexts, it has been very difficult to reverse language shift once it has taken hold in language minority communities. Canada, Mexico, and the United States all provide strong examples of the shift from L1 to English or to Spanish. In North American contexts, several authors have argued for the need to maintain and revitalize languages endangered by major languages (Fishman, 2001). To date, maintenance and revitalization efforts have not proven very successful, though considerable effort has gone into preserving specific minority and indigenous languages.

Language Use in Professional Contexts

Important work has been ongoing in the study of language use (and abuse) in professional and academic settings. Significant work has been undertaken in legal settings, medicine, and science (McGroarty, 2002). Legal language use has focused on evidence collection and interrogation, language practice in court settings, and bilingual interpreting. In medical settings, language issues focus on gaining appropriate services and support for language minority patients; the power differentials and the conversational interactions between patient and care provider; the role of oral narrative to explain a patient's situation; a care provider's interpretations; and the formation of new

identities as a result. Research on language and science focuses on the linguistic analysis of scientific writing and scientific genres. A second line of research involves the rhetorical analysis of scientific writing.

Corpus Linguistics

Corpus linguistics has emerged as an important area in applied linguistics over the past decade. A major direction for corpus linguistics has been the use of corpora in writing grammars and dictionaries, in exploring genre and register differences, and in language teaching resources (Conrad and Biber, 2001). Corpus linguistics has been used for a variety of specific purposes: the role of discourse markers, the nature of textbook language, the role of power and status in language, the study of lexis in texts, and the selection of text segments in teaching materials and assessment tasks. These activities can be carried out through the use of large corpora or of smaller corpora collected for specific purposes. Hinkel (2002) provided one excellent example of an analysis of L2 student writing development from a smaller corpus of student texts.

Critical Perspectives in Applied Linguistics

Over the past decade, the movement toward critical theories has migrated strongly from cultural studies, literacy criticism, and philosophy into applied linguistics. At present, one can find discussion of critical discourse analysis, critical pedagogy, critical language assessment, and critical policy and planning. These trends are also closely tied to issues of identity and language learning with respect to activism for the learner perspective. Over all, there is somewhat less activity in critical perspectives in North America than in Europe, but it is, nonetheless, growing in importance. Critical discourse analysis (CDA), the earliest of the critical approaches within applied linguistics, has not gained widespread recognition in North America. Its critical orientation and political activism has not influenced the strongly functional orientation to North American applied linguistics, and its stress on scientific methods by North American applied linguists does not resonate with critical theorists coming from cultural studies and composition backgrounds.

Two lines of critical orientations have been more influential in the United States: L2 writing instruction and L2 immigrant-education teaching methods. Kumaravadivelu (1999, 2001) was one of the few North American applied linguists to draw directly on CDA to interpret and then influence teaching methods and teacher actions directly. In the area of L2 writing instruction, a number of L2 writing theorists have drawn on postmodernist theory to assert the rights of students in the classroom to their own cultural, social, and political identity. Thus, there is a movement away from more pragmatic needs analysis to a critical-pragmatic view of the teaching and learning of writing, along with activism to change what are seen as oppressive institutional structures (Benesch, 2001; Canagarajah, 2002). A major criticism of critical orientations is that they cannot generally point to better learning outcomes and more effective outcomes with respect to real world language problems. However, in the area of ESL instruction, Benesch (2001) explained a number of course curricula that engaged and challenged student learners while promoting critical agendas (see also Canagarajah, 2002).

New Trends in Applied Linguistics in North America

The field of applied linguistics is constantly evolving. Space does not permit a full exploration of these emerging trends, but they should be noted in this conclusion. Sign languages are emerging as an important area in which major language problems deserve greater attention and this trend will grow. There is now a more general recognition for fairness and ethical responses to language issues, whether the issues involve instruction, assessment, policy, or appropriate access, and this recognition will grow in the coming decade.

Additional trends in applied linguistics include the growing recognition that linguistic theories may be important for some issues, but that descriptive linguistics (including the use of corpus linguistics) contributes more widely to addressing real-world language problems. Similarly, there is a growing recognition of the importance of language assessment as a means not only to measure student development in fair and responsible ways, but also as a resource for appropriate measurement in research studies and in the development of effective tasks that influence teaching and learning.

The interdisciplinary nature of applied linguistics continually brings in further research perspectives and methodologies from related fields. The interdisciplinarity of the field, the emerging trends in the field, and the increasing specializations in the major subfields of applied linguistics, raise important questions about the training of future applied linguists. It is inevitable that applied linguists, if they are to address real-world language problems in an increasingly complex world, will need more complex and specialized

training. It may perhaps be a requirement that major applied linguistics research and application efforts involve teams of applied linguists in order to marshal the necessary resources and expertise. How the training of future applied linguists will evolve to work in these more complex environments is a significant issue that will require greater attention in the coming decade.

Applied Linguistics in South America

M C Cavalcanti, Universidade Estadual de Campinas, Campinas, Brazil

© 2006 Elsevier Ltd. All rights reserved.

To write about what happens in a field of knowledge like applied linguistics in South America proves to be difficult, not so much because of the geographical distance among the countries but mainly because there does not seem to exist a tradition of intensive academic interchange in this part of the world. Geographical distance itself should not be a problem in this era of Internet communication. However, within a postcolonial perspective (Hall, 1996; Venn, 2000), this lack of interchange may be seen as part of our (i.e., South American's) naturalized colonial memory in postcolonial times. Otherwise, how could one explain that whenever considering going abroad to complement one's studies, taking such a journey meant (and to a certain extent still means) going North? Or how could one explain that many a time, it may be easier to find out about research being developed in the countries which constitute South America in conferences either in the United States or in Europe rather than in South America itself? In other words, each country seems to look 'North' instead of looking 'South' where our nearest and farthest neighbors are. This distinction between North and South (the ideological vision of the northern and southern hemispheres) is used here, as suggested by Santos (2004), the South being a metaphor for the consequences of capitalism and globalization to mankind.

To gather information about South American Applied Linguistics, to get a glimpse of the area on the continent, the first move was to go through an Internet search of universities and/or research institutes that listed Applied Linguistics as keywords. The second move was to look for journals in South America.

The first move resulted in a few references to university courses in Argentina, Bolivia, Chile, Colombia, Ecuador, Peru, Venezuela, Uruguay, and Brazil and to one research institute in Argentina. (Quite a few language schools also came out in the search but were discarded, as the focus here is on research studies.) As it can be observed, the search left out countries such as Paraguay, Guyana, Surinam, and French Guyana. Another observation is that apart from Brazil, there was no mention of the theses and dissertations produced. Considering that the information available through the Internet depends on continuous feeding, no expectations were built that the search would be exhaustive or that it would reflect the state of the art in Applied Linguistics in South America. In any case, the first impression developed from this search was that Applied Linguistics is strongly taken in relation to the teaching of foreign languages. However, it should be recorded that there are also some applied linguistics links to translation studies, the teaching of Spanish as mother tongue, and bilingual studies, including language planning and language policy.

The second move resulted in only one potentially relevant URL (see the Relevant Websites section of this article). Having as a title *Latin America: subject resource*, the site describes itself as a 'Latin American–based resource interesting and useful as a Reference Librarian.' It has a link to the Association of Research Libraries Project, whose first item is the 'Latin American Periodical Table of Contents (LAPTOC).' However, closer scrutiny showed very general information about journals in South American countries. For example, there was no mention of specialized journals in Applied Linguistics in any country, not even in Brazil. Elsewhere (Cavalcanti, 2004), there is reference to seven Brazilian Applied Linguistics journals, four with AL as part of their titles. A more general list of journals, including Linguistics, Applied Linguistics, and Literature, can be found at the website of the Commission for the Upgrading of University Graduate Level Personnel (CAPES), Brazil.

Previous to the Internet search, a few publications on or related to Applied Linguistics had already been gathered and examined. These publications, which either have Applied Linguistics as part of their titles or which have chapters that can be placed in this field of knowledge, are examined below under two subtitles chosen to indicate whether they were published in or out of South America. As to be expected, they are also a very relevant source of other references to be pursued.

Some Publications in South America

This section includes publications originating in isolated countries in South America as well as publications which, although from single countries, have some micro or macro representation of countries in the continent. The micro representations refer to the ones that gather scholars within geographical delimited regions, as Jung *et al.* (1989) and López (1988) both in the Andes, and the macro representations indicate the attempts to put together scholars from different regions on the continent.

Three books published in Peru in the late 1980s, i.e., Jung, Urban, and Serrano (1989), López, Pozzi-Escot,

and Zuñiga (1989), and López (1988), focus on issues relevant to two related subareas of Applied Linguistics, namely indigenous bilingual education and language policy/planning for bilingual and monolingual contexts. The first and the second include Applied Linguistics in their titles: *Aprendiendo a mirar: una investigación de lingüística aplicada y educación* and *Temas de lingüística aplicada – primer congreso nacional de investigaciones lingüístico-filológicas*. In the first, Jung, Urban, and Serrano (1989), reported on the educational aspect and on research work developed in the well-known Puno Project, a bilingual education program in Peru. The second, López, Pozzi-Escot, and Zuñiga (1989), focused on monolingual and bilingual contexts in Peru with sections on language planning and policy. The third, Lopez (1988), collected papers on bilingualism and bilingual education. As Lopez (1988: 8) emphasized: "Pocas son las instituciones que aceptan y asumen la pluralidad lingüística y cultural del país. Resulta significativo la desatención secular de la población indígena . . ." [Few institutions accept and assume the linguistic and cultural plurality of the country. The result is the century long lack of attention towards the indigenous population . . .]. (Ten years later the same can be said about Brazil, as put forward by Cavalcanti, (1999: 387): ". . . there is a myth of monolingualism in the country . . . [which is] efficient to invisibilize minorities, for example, the indigenous groups, the immigrant communities . . .")

Also with a focus on bilingual education but covering a wider scope (see also Cavalcanti, 1999) ranging from elite bilingualism through deaf people's schooling to minority bilingualism, Mejía and Tovar (1999) edited a publication in Colombia. Curiously, there is no mention of Applied Linguistics in the chapters written by Colombian scholars. (Two chapters only are from non-Colombians, one of them by a South American.) In other words, many of the chapters in the publication could belong to an Applied Linguistics collection, and this state of affairs brings in an argument that people do AL after all but do not call themselves applied linguists.

It is important to emphasize that the publications above are portraits of specific locations in Spanish-speaking South America. It would be no different if some Brazilian publications were to be listed (see for example, Bohn and Vandresen, 1988; Paschoal and Celani, 1992; Signorini and Cavalcanti, 1998; Leffa, 2000). These books contain mainly reports of research undertaken in Brazil. It should be added that if they do have chapters from foreign scholars, they are ones from 'the North.' Some of the chapters in these books address epistemological issues in Applied Linguistics.

Besides local publications, there are ones that originated in one country but contain works by representatives from other countries, as for example, Trindade, Behares, and Fonseca (1995), Seki (1993), Zuñiga *et al.* (1987), *Trabalhos em lingüística aplicada* [Works in Applied Linguistics] (1989), *Anais da IX ALFAL* [Proceedings of the IX Congress of the Association of Linguistics and Philology of Latin America] (1992). All of these, with the exception of Trindade *et al.* (1995) are proceedings of (inter) national conferences. It should also be observed that only one of these publications is within the area of Applied Linguistics. The others come from Linguistics and Education (Trindade *et al.*, 1995), from Linguistics with some papers in Applied Linguistics (Seki, 1993), from Linguistics and Philology with a section in Applied Linguistics (*Anais da IX ALFAL,* 1992), from Education (Zuñiga *et al.*, 1987). These publications have chapters focusing on literacy, language education, language planning, language policy, mother tongue education, foreign language learning – that is, in subareas commonly found in Applied Linguistics publications.

It should be pointed out that in all of the publications above, (with the exception to the first one (Trindade *et al.*, 1995), which focuses on joint research developed by scholars from Uruguay and Brazil), the preferred reference seems to be Latin America and not South America. Actually, it is difficult to limit one's eye to South America when it is the adjective Latin that appears to have been the point of convergence in Latin America as seen below.

Four Publications outside South America

In the publications selected for this section, three focus on Latin America and one on the Americas. They all either have a special section on South America or include South American contributors.

The first publication presented, the fourth volume of *Current trends in linguistics*, published in the late 1960s, has a historical value regarding Applied Linguistics in its initial stages in the continent. The volume, which has a survey report on 'Foreign language teaching in Latin America,' was written by Gomes de Matos and Wigdorsky (1968). The survey is very comprehensive regarding South American (and also Latin American countries) and is in line with the equation Applied Linguistics equals foreign language teaching, which was current at the time.

With a gap in the 1980s, the reader is invited to land on the 1991 special issue on *Políticas del lenguage en América Latina* [Language policies in Latin America] of *Iztapalapa*, a journal from the area of social sciences published in Mexico. The issue puts

together linguists, applied linguists, and social scientists from Argentina, Brazil, Peru, and Uruguay, and also from Mexico and Canada.

Then, there is a jump to the 21st century with two publications, one from North America about the Americas, i.e., Hornberger (1997), and the other from Latin America (Mexico), i.e., Curcó, Colín, Groult, and Herrera (2002).

The focus of Hornberger (2000) was the indigenous literacies in the Americas, with a specific section on South America. The South American countries represented are Peru, Ecuador, Bolívia, i.e., Andean countries. The emphasis in this case is on indigenous contexts, as in some books already mentioned (Lopez, 1988; Jung *et al*., 1989). Actually, it should be noted that studies on indigenous contexts seem to be a strong point of convergence among South American (and also Latin American) scholars, as it can be seen in publications such as Seki, (1993) Zuñiga *et al*., (1987), *Trabalhos em lingüística aplicada* (1989: 14), and *Iztapalapa* (1993: 29).

The second publication from the 21st century came out in Mexico, a Latin American country that was originally set out of my scope of South America. However, the country seems to be the focus of interaction between South American countries like Brazil, Uruguay, Argentina, Bolivia, Peru, Ecuador, and Colombia, to mention a few. Brazil and Mexico, for instance, have had a long time partnership in matters of Applied Linguistics, which includes exchange of scholars and students and conference participation. Actually, conferences in Mexico seem to have been a place of academic encounter for South American scholars.

It should be emphasized that Mexico has thus pioneered getting together Latin American scholars, out of a conference context, in an assumedly Applied Linguistics publication: Curcó, Colín, Groult, and Herrera (2002): *Contribuiciones a la linguistica aplicada en América Latina* [Contributions to Applied Linguistics in Latin America]. When comparing the contents of this book, with its South American bias, with the results from the initial Internet search, two things are of note: a) that the list of countries represented, be they the contributor's place of work or place of origin, was very close to what came out of the Internet search (see above): Argentina, Brazil, Chile, Colombia, Peru, Venezuela, and Uruguay; and b) that the coverage of Applied Linguistics subareas was more pervasive than in the Internet search, i.e., beyond the strong focus on foreign language learning, there were contributions from South American authors under the following headings: mother tongue learning; teacher education; bilingualism, minority languages and language policy; contrastive analysis; interaction and discourse analysis in the Anglo-Saxon tradition. It should be highlighted that in this collection of papers, there is an addition of the subarea of minority languages in bilingual contexts, for example, indigenous communities (Brazil) on the one hand and deaf people (Colombia) on the other hand. Furthermore, Psycholinguistics and Sociolinguistics are also presented as Applied Linguistics (within the view of application of Theoretical Linguistics). However, this same book has chapters whose authors (Moita Lopes, 2002; Kleiman, 2002; Gabbiani, 2002) hold other views of Applied Linguistics, i.e., including that of another area of knowledge (Cavalcanti, 1999, 2004).

The Path of Applied Linguistics in South America: The Shadow Metaphor

A chapter by Gabbiani (2002), in the above mentioned Curcó, Colín, Groult and Herrera (2002), is the departure point for this section. In the chapter with a thought provoking title: 'Linguistica aplicada en Uruguai: trayectoria de una existencia anonima' [Applied Linguistics in Uruguay: The journey of an anonymous existence], the author (2002: 431) states:

> . . . the lack of a team of researchers who exchanged ideas about the theme and a strong positioning against the term applied linguistics resulted in the option of not using it. This way the investigation in this area remained concealed (one could say 'anonimized' . . .). I insist that this does not mean that this investigation does not exist. [Article author's translation of Spanish quotation. As an example of research developed in Uruguay, see Behares, 1982 and Gabbiani, 1994]

The journey of Applied Linguistics in Uruguay raises the question that perhaps the field has an anonymous existence not only there but also in the other South American countries. Nevertheless, to be fair to the diversity of approaches that may describe Applied Linguistics in South America, I would extend Gabbiani's metaphor of anonymity to a shadow metaphor. This extension would mean that to work in the shadow would encompass other situations besides the one pointed out by Gabbiani. In other words, the anonymity in Uruguay is related to doing AL within other disciplines when AL is not a preferred term. However, in other countries in South America, the work in AL may also be done in the shadow when researchers do not assume themselves as applied linguists and when they do AL under the label of other disciplines that they see as more prestigious. It should also be noted that even when we researchers position ourselves as applied linguists, we may also comply with working in the shadow when we take time to publish our research work within a very inefficient system of

circulation and distribution of publications outside (and sometimes inside) our own countries, when we all comply with little academic interaction among AL postgraduate programs, when the university websites are not updated to include new theses and dissertations immediately after they are approved, when there is lack of financial support for research and circulation of research results. In other words, what I mean by working in the shadow is related to the invisibility of the area of Applied Linguistics and therefore to the difficulty in getting information about the research work carried out.

About Brazil, an observation has to be made about the route of Applied Linguistics where the shadow metaphor would only be partially applicable. As I mention elsewhere (Cavalcanti, 2004: 27; Gabbiani, 2002), Applied Linguistics is a consolidated field of knowledge in the country:

> ...the late nineties indicate a consolidation of applied linguistics as an area of knowledge of its own [in Brazil]. This is reflected in the growth of research (see Leffa, 2000), publications and in the presentation of results in national conferences, in the recognition of the area by funding bodies, and in the evaluation from within the area which came out in papers (Celani, 1992; Kleiman, 1992; Moita Lopes, 1994; Signorini and Cavalcanti, 1998). Undoubtedly a consequence of the growth of human resources formed in the postgraduate programmes in the area, the growth of research was also shown in the submission of proposals to the national funding bodies and in the participation of scholars in academic forums.

The partial application of the shadow metaphor in the case of Brazil is related to some researchers carrying out AL research in other more prestigious areas like theoretical linguistics studies, thus not assuming themselves to be applied linguists, which may be an indicator of the importance given to Linguistics, Applied Linguistics thus occupying a subordinate position. The partial application may also be related to researchers complying with an inefficient system of distribution of publications and to the small interaction among postgraduate programs, which results in a poor circulation of information about theses and dissertations produced.

One last point in this section is illustrative of the point made about theses and dissertations written in Brazil. Both could be seen as additions to Trindade *et al.* (1995), the only case of crossborder publication in the references cited in the previous section. One, Orlando (2001) led to an M.A. thesis and the other, Pires Santos (2004), to a Ph.D. dissertation. Orlando focused on Brazilian university students learning Spanish as a foreign language in Uruguay, and Pires Santos looked at a minority context in Brazil, i.e., the *brasiguaios*, Brazilians who go to Paraguay in search of a better life and end up returning to Brazil. Other works like these are in the shadow, and sometimes may take a long time to surface.

Final Remarks

Although there is an AL movement in South America, the surface is hidden away by lack of academic interchange, be it in conferences, be it in the spreading of local publications, be it in the access to theses and dissertations. AL studies in the different countries in South America, Brazil excepted, are developed in other fields of research, for example, in education and in anthropology (See, for example, *Lenguas aborigenes de Colombia – memorias* [Aboriginal languages in Colombia: Proceedings 3, VII Anthropology Conference], 1995); or other departments such as Linguistics or Languages, by researchers who do not necessarily see themselves as applied linguists. Hence again the shadow metaphor represents Applied Linguistics in South America.

The field in this location seems to have found more room to consolidation (Cavalcanti, 2004) in Brazil (and in Latin America, Mexico would have to be included) within at least two views of AL, a field of knowledge in its own right and a locus for applying linguistic theories. The other countries in South America, as of today, apparently favor theoretical linguistic studies. Nevertheless, within publications in the area of theoretical linguistics, for example, it is possible to identify chapters reporting studies that could be placed within these different views of Applied Linguistics.

What theme or themes may be convergent in attempts to establish academic interchange? The answer to this question may be given from at least two different standpoints.

One of these views is within the Mercosul/Mercosur, the South American Common Market, which only includes Argentina, Brazil, Paraguay, and Uruguay, and has shown that job opportunities signal that people should know Spanish/Portuguese. In that case, research on language teaching and learning regarding Spanish and Portuguese are on the agenda. Actually, Spanish and Portuguese as foreign languages have been one point of convergence among teachers and researchers mainly in the countries that are part of the South American Common Market. However, publications that gather researchers from these different countries and record efforts made towards, for instance, reporting research in the area in South America, seem to be rare. Two publications should be mentioned here, Gabbiani (1995) and Almeida Filho (1995). Gabbiani (1995), is an article

in a conference proceedings and focuses on the teaching of Spanish and Portuguese as foreign languages in Uruguay. The other is a publication edited by Almeida Filho (1995) that puts together research on the teaching of Portuguese for Spanish speakers. The latter only has contributions from Brazilian scholars except for one chapter from a Mexican researcher.

The other view is related to the social problems the countries share in the 'South.' Among these problems, there are certainly many convergent issues that are potentially relevant for applied research. These issues range from literacy in urban and non-urban (rural and indigenous) contexts, for example. Within these contexts, there are a number of subcontexts. Just to name two: deaf people and schooling; and indigenous peoples and teacher education. Therefore, the publications' references to the indigenous populations may not have been gratuitous. Looking at the field of AL from within South America, there is an urgent need to establish partnerships in this South, to learn from and to exchange experience with one another.

Introduction

In the context of South Asia, applied linguistics can be defined as an area of activity pertaining to language-related concerns that go beyond the study of the forms and functions of language for their own sake. The discipline has developed new perspectives and frames of reference for various areas of language-related concerns, including language teaching, stylistics, literacy, translation, lexicography, language policy, and computational linguistics. Applied linguistics provides help to those who are in need of such new knowledge in their language-related practices. Although it is true that applied linguistics presupposes a knowledge of linguistics, it is also true that applied linguistics helps in developing linguistic theory. It does this not only by providing insights from other disciplines, but by also providing new and challenging data. The increasing scope of applied linguistics can be recognized from the presidential address delivered by Dwight Bolinger to the Linguistic Society of America on December 28, 1972 in which he stressed the fact that while subjects and verbs agree, linguists should also deal with the questions of whether statements and facts agree. Once we

move in this direction, the 'big lie' becomes the proper object of study for linguistics – and a necessary one, especially when lying is cultivated as an art by governments, politicians, journalists, writers, and even linguists (Bolinger, 1973). In a similar context, Srivastava (1990: 11) in his 'Address to the Indian Linguists' viewed applied linguistics as a "socially meaningful academic activity, since here linguists are called to utilize their knowledge and skill to reveal the implicit assumptions made by speakers for the benefit of common users." This brings applied linguistics right into the center of language-related social concerns. The scientific perspective of linguistics, it is believed, will help in solving language-related social concerns.

Applied Linguistics in the Subcontinent

The term 'applied linguistics' came into use in the late 1940s and in the 1950s in both Britain and the United States, where it initially referred to the teaching and learning of second or foreign languages. However, it got prominence in India through the Linguistic Society of India (formed at the Fifth Oriental Conference held at Lahore in 1928 with its first journal, *Indian Linguistics* (*IL*), which commenced publication in 1931). In pre-independence and undivided India, the activities of the Society were mainly centered on descriptive and historical linguistics. Major activity in the growth of linguistics as an independent discipline began in 1951 after the meeting of the Society at Deccan College in Pune. Since the English language was supposed to cease functioning as the official language of India in January 1965, the meeting identified the fundamental need to apply knowledge of linguistics for the solution of the related problems of communication and for the development of regional languages. Subsequent political developments led to the amendment of the Constitution in 1967, whereby English was declared the "associate official language," which it continues to be until today. The Summer Institutes in linguistics came into existence in 1954, and departments of linguistics began to be set up in Indian universities (the department at Calcutta University was established in 1920). Linguistics as a major discipline was taught in 14 universities by 1982; the number rose to 20 in 1992, and today it is around 32. Applied linguistics is a major component of these programs.

Major publishing of works about applied linguistics began with *Some aspects of applied linguistics* by D. P. Pattanayak (1969) and *Aspects of applied linguistics* by A. M. Ghatage (1970). The Dravidian Linguistics Association was formed in 1971, and the first issue of *International Journal of Dravidian Linguistics* (*IJDL*) appeared in January 1972. With a high demand for publications in applied linguistics, Ujjal Singh Bahri founded the *Indian Journal of Applied Linguistics* (*IJOAL*) and the *Language Forum* (*LF*) in 1975. The biannual *South Asian Language Review* (*SALR*) under the editorship of O. N. Koul began publication in January 1991. While *IL, IJDL*, and *SALR* publish papers on theoretical as well as applied linguistics, the *IJOAL* caters only to applied linguistics, and *LF* publishes papers on applied linguistics and on literary studies. At present, there are a number of other significant publications, including *CIEFL Bulletin, Osmania Papers in Linguistics, The Yearbook of South Asian Languages and Linguistics, Psycholingua*, and *Applied Linguistics*. The creation of the Central Institute of English and Foreign Languages (CIEFL) in 1958, the Central Hindi Directorate (CHD) in 1960, the Central Hindi Institute (CHI) in 1961, and the Central Institute of Indian Languages (CIIL) in 1969 have further strengthened the work on applied linguistics through research and publications. The robustness of the field can also be seen in the numerous publications of Sage Publications, Bahri Publications, Creative Publications, Oxford University Press, and the CIIL. The range of publications on applied linguistics shows that the discipline initially equated with language teaching and language learning has expanded in scope to include other issues as well as issues related to multilingualism, language planning, language contact studies, second language acquisition, stylistics, translation studies, language disorders, and computational linguistics.

Multilingualism and Language-Related Concerns

South Asia provides a unique instance of the fusion and diffusion of linguistic traits across genetic boundaries between speakers of various Aryan, Dravidian, Austro-Asiatic, and Tibeto-Burman languages. As such, it leads to what Emeneau (1956) describes as the genesis of India, or even the whole of South Asia, as a 'linguistic area.' This linguistic area not only has common linguistic traits but also common sociolinguistic traits (Pandit, 1977). The sociolinguistic facts of South Asia can be different from those of countries in the west, e.g., Pandit (1977: 9) observes that second-generation speakers in the west give up their native language in favor of the dominant language of the region, showing thereby that "language shift is the norm and language maintenance an exception," while in South Asia, "language maintenance is the norm and shift an exception." Scholars like Pandit, Kachru, Srivastava, Pattanayak, and Khubchandani have tried to understand the multilingual and

pluricultural nature of the subcontinent, with its mosaic of linguistic heterogeneity and cultural complexity. They found bilingualism and multilingualism to be the natural state of verbal behavior and reacted sharply to earlier Western interpretation of bilingualism as a symbol of poverty and discrimination (see Pattanayak, 2004: 44–54). It may be appropriate to say that speakers in South Asia are endowed with a 'multilingual communicative competence.' Scholars have pointed out that the language ecology of the subcontinent consists of grassroots bilingualism. In this language situation, each major language acts merely as a link language; the linguistic reorganization of states converted the link languages into dominant official languages, i.e., languages of political power and prestige. As dominant languages, they begin to block upward social mobility of the members of other speech communities. This blocking sometimes creates major intergroup rivalries and language movements such as the one that led to the breakup of Pakistan in 1971 into Pakistan and Bangladesh. Other examples include the division of the Indian state of Punjab into Punjab and Haryana or the ongoing Tamil-Sinhala conflict in Sri Lanka. The linguists of the subcontinent, through application of their knowledge, have been able to understand the language-related problems of the subcontinent. Linguists have examined issues related to language policies and language in education, language teaching, language in contact situations, stylistics, translation studies, psycholinguistic issues related to language disorders, and so forth.

Language Policies: Scheduled and Nonscheduled Languages

The South Asia region, with minor variations, shows the hierarchical relationship between languages as established by language policies. This asymmetrical relationship leads to the empowerment of some languages at the expense of others. The cases of India and Pakistan can be taken as instances.

The Indian Constitution, adopted in 1950, recognized the multilingual nature of the nation and listed 14 languages with distinct literary traditions in its Eighth Schedule. These are termed 'scheduled languages.' The number of languages was increased to 15 in 1967, to 18 in 1992, and to 22 in 2004. Other languages are actively seeking to be listed as well, because of the political and economic benefits that accrue to speakers of scheduled languages.

The 1991 census lists 96 nonscheduled languages. Aside from Arabic, English, and Tibetan, there are 90 tribal languages that are distributed in the four language families of Indo-Aryan, Dravidian, Austro-Asiatic, and Sino-Tibetan (for details, see Khubchandani, 2001: 1–47). There is a fear that due to lack of support and due to apathy of the users, some of these may face extinction like Gutob and Bonda appear to have (Pattanayak, 2001: 48–49).

Tariq Rahman's (2003) paper reveals a similar situation in Pakistan. Pakistan has six major languages and over 59 minor languages in its multilingual profile. The policy of the state favors two languages, Urdu and English. Urdu is claimed by only 7.57% of the population as mother tongue, and it is projected as a symbol of ethnic identity. English is made to represent modernization and efficiency. These factors are leading to language shift, and languages like Aer (200 speakers reported in 1998), Gowro (200 speakers reported in 1990), Kundal Shahi (500 speakers reported in 2003), and others appear to be on the verge of extinction. Linguistics can help focus on the state of linguistic human rights in the region and suggest means of empowerment of minority languages.

Language and Education

The domain of education poses the greatest challenge for applied linguistics in the post-colonial phase of multilingual South Asia because of the role of English in affecting education and education policies.

Language and Educational Policy

Post-colonial South Asia had initially wanted the dominant regional languages to take over the function of education from the English language. Due to language confrontations and lack of political will, English has continued to be an increasingly potent medium of instruction in the countries of the region. For example, in India there have been numerous deliberations regarding the study of language at the school level as well as at the higher levels of education. Keeping in mind the multilingual profile of the country, the Central Advisory Board of Education (CABE) proposed the 'three language formula' for the Indian education system in 1957. It was formalized by the (Kothari) Education Commission (1964–6) (for extracts and recommendations, see Aggarwal, 1993: 175–193). Under this formula for school education:

- The first language to be studied must be the mother tongue or the regional standard.
- The second language:
  (i) In Hindi-speaking states, will be some other modern Indian language (MIL) or English

(ii) In non-Hindi-speaking states, will be Hindi or English.

- The third language in Hindi-speaking states will be English or an MIL and in non-Hindi-speaking states English or Hindi, i.e., a language not studied as the second language earlier.

The implication of this formula has been that while the teaching of the first language commenced from Class I, the teaching of the second language was recommended from Class VI or a bit earlier, from Class III, or at a convenient stage depending upon the resources of a state. The third language was also recommended to be taught from Class VI (for details, see Gargesh, 2002: 191–203). Since education is a subject under the state governments and not under the central government, the actual implementations have varied from state to state. However, presently there is an increasing trend toward beginning the teaching of English as a subject from the earliest possible class in schools.

Further, the three-language formula has created a situation where a child belonging to a linguistic minority may have to forgo instruction in the mother tongue due to lack of resources or infrastructure. The formula does not do justice to thinly spread out minorities. Further, as one goes higher on the educational ladder, only major languages are studied, while finally at the top (for science and technology) there is only English. Although there is space for English in present-day India, Agnihotri (2001: 187) rightly bemoans that "this space has largely been used to create a divide in society. The acquisition of English by a small elite and rich minority helps it to consolidate its power and perpetuate injustice and exploitation in society." The situation in Pakistan (Rahman, 2003: 4) and in Bangladesh (Shahed, 2001: 8–9) is similar. However, given the fact that the demand for education delivered in English is increasing, scholars have reviewed its role as well as the state of its teaching. What can be said of India is more or less representative of the whole of South Asia.

Role of English in Multilingual South Asia

Various conferences and committees have grappled with the question of English as a foreign language, library language, link language, second language, Indianized language, and so forth. The role assigned to a language reflects several implicit assumptions about the kind of bilingualism and the kind of language teaching that is required. Srivastava (1994: 94) identifies four distinct functional roles for the Other Tongue (OT):

a. Auxiliary Function: The OT is used for the sake of gaining knowledge rather than for communication. The learning of classical languages serves such an end, which produces 'passive' bilinguals.
b. Supplementary Function: The OT is used occasionally and sporadically for fulfilling the restricted needs of tourists, diplomats, and so forth. This creates 'partial' bilinguals with partial competence in the target language.
c. Complementary Function: The OT complements the first language when it is habitually used in restricted but well-defined sociological environments. This creates 'stable' bilinguals with partial competence in the target language.
d. Equative Function: The OT can be said to be equative when it is employed as an alternate language in all domains in which the first language is used. Such a situation creates 'ambilinguals.'

Elsewhere, Srivastava (1994: 297) looks at these functions in relation to the variables 'language type,' 'bilingualism,' 'bilingual,' and the 'teaching method' required as shown in Table 1.

English, due to its widespread use in the media and education, is largely a second language in South Asia. However, the teaching of English is not effective and lacks direction. Nonetheless, significant steps have been taken toward changing that.

Language Teaching in South Asia

Within South Asia, some changes in the teaching of English have emerged from the disciplines of linguistics and applied linguistics. The initial changes at an all-India level and their failure are reported in three documents: (1) *The Teaching of English in India* brought out by the National Council for Educational Research and Training (NCERT), Delhi, in 1963, (2) *The Study of English in India* brought out by the Ministry of Education, Government of India,

Table 1 Functional roles of the Other Tongue (OT) – a slightly modified version

Function	*Auxiliary*	*Supplementary*	*Complementary*	*Equative*
Language	Library language	Vehicular language	Link language	Alternant language
Bilingualism	Cultural	Isolated	Societal	Equative
Bilingual	Passive	Unstable	Stable	Ambilingual
Teaching method	Classical language	Foreign language	Second language	Bilingual education

in 1967, and (3) CBSE-ELT Project (1989–97), a report prepared by the *Central Board of Secondary Education* (CBSE), Delhi.

The first two reports inform us that initially in post-independent India, there was a shift from the grammar-translation method to the 'direct method.' This change resulted in an anomalous situation in which grammar ceased to be taught in the classroom. Oral drills, which were devised to replace the teaching of formal grammar and to habituate the learner to correct usage through actual practice, were not widely adopted. What remained of the teaching method was only the reading and translation of the prescribed literature-oriented textbook. To both meet the long-standing demand for making classrooms significant learning sites and reorient pre-service and in-service teacher training, the CBSE (in the third report) engaged in a major curriculum renewal project, CBSE-ELT Project (1989–97). The Project received British assistance through the British Council in India. The result was a new syllabus for Classes IX and X. The syllabus had a focus on the development of language skills in communicative situations and became a model for other boards of education in other parts of India. The problem generally confronted today is that students score well in exams but are not able to write a high-quality, lengthy discourse in English. Since the pedagogy employed in the teaching of English has also been a model for the teaching of other Indian languages, the future role of the applied linguist will always remain highly significant.

Research Related to Language Learning and Acquisition

Much research in the areas of applied linguistics in the 1960s and 1970s in South Asia focused on contrastive analysis and error analysis, which invariably involved English and a South Asian language. With the increase in focus on the Chomskyan paradigm, work also began to shift into the area of second language acquisition, where the role of applied linguistics was restricted to the validation of linguistic theory or (at best) helping to extend the database against which linguistic theory could be tested (Singh, 1991: 5–15). This led to an interest in the study of interlanguage and in identifying strategies that second language learners use in their communication (Singh, 1991: 17–38). The emphasis on theoretical aspects can be seen in a number of doctoral dissertations at the CIEFL Hyderabad that focus on the differences between a South Asian language like Hindi (or Malayalam, Telugu, Kannada, Oriya, Nepali, and so forth) and English, in terms of syntactic or phonological structures with "the larger vision of universal grammar, which renders all languages (past, present and future) equally possible" (Amritavalli, 2001: 245).

Another area of research has been the attitudes towards second language acquisition. The South Asian experience reveals that a second language like English is learned and is considered significant in the region not because of an 'integrative' function but largely due to the 'instrumental' function. It is a means for enhancing social mobility and individual personality (Agnihotri and Khanna, 1997: 85), and for providing better education and more information (Abbi *et al.*, 2000: 20, 22). The findings are similar for Pakistan (Mansoor, 2004: 355) and Bangladesh (Shahed, 2001: 131, 135).

Languages in Contact

The area of languages in contact in South Asia has also emerged as an important area of applied linguistics. This is because it is here that we find linguistic implications relating to economic, socio historical, and political factors. The study by Gumperz and Wilson (1971) of language use in Kupwar, a small Indian village on the border of Kannada (Dravidian language) and Marathi (Indo-Aryan language), reveals that the communicative needs of the people have led to a merging of the grammars of three languages: Kannada (used by Jains), Urdu (used by Muslims) and Marathi (used by the lowest strata). Some more recent work in the area covers languages used on the tea plantations of Assam and other contact languages like Silchar Bengali, Nagamese, and Sadri. Indian English and any other New World English could also be situated in similar circumstances. An interesting case is that of Nagamese, a variety that has come up as a code for interlingual communication among different linguistic groups of the Nagas in Eastern India. While Satyanath (1999) examines the Pidgin/Creole characteristics of the language, Kapfo (2001: 155–169) identifies the variety largely as a language of wider communication among the uneducated, with the educated using it mostly in ordinary domains like the marketplace. The work on contact languages addresses the questions of the sources of the lexicon and grammar, and the role of the processes of second- and first-language learning. The work also raises linguistic questions about the stripping of inflectional morphology and other complexities, which results in simple grammars, or about understanding how linguistic variation in such contact languages generates polylectal grammars.

A related area of great interest within the domain of contact languages has been South Asian English, a variety of English that takes into account Indian,

Pakistani, Sri Lankan, Bangladeshi, Nepali, and Bhutanese Englishes. In the context of India, Kachru calls the convergence process 'Indianization' (Kachru, 1983). While most work has been on the phonology and lexicon of these varieties, work on the presence of syntactic forms, such as on the use of the progressive verb for the nonprogressives used elsewhere, the use of reduplicative forms, the frequent use of the *isn't it*? in tag questions, and the peculiar use of negations and so forth, have been enumerated by Kachru (1965), Verma (1978), and Aitchison and Agnihotri (1994), and others. Kachru (1994) looks at the varieties of language in terms of configurations of discourse strategies in larger pragmatic and cultural contexts, e.g., a discourse strategy of South Asian writing is the 'mixing of styles' such as the 'ornamental' with 'impersonal' in expository prose.

Stylistics and the Teaching of Literature

Another significant area of research in applied linguistics on the subcontinent has been the domain of stylistics, which is largely viewed in terms of a linguistic approach to the study of literary texts. Its popularity can be gauged from the fact that the inaugural issue of the *Indian Journal Of Applied Linguistics* (*IJOAL*) (1975) was devoted to it. This was in tune with the major concern at that time: making literary studies more objective, scientifically rigorous, and language-oriented. This was necessary because the field was full of subjective and arbitrary studies. The application of linguistics to literary texts was seen as a challenge to the discipline of linguistics which had by and large shied away from literary data. Because all literature is manifested **in** and **through** language, it was felt that there was no need to draw a dividing line between the literary and the linguistic functions. From the first issue of *IJOAL* until now, much work has been done in the area of stylistics.

The work on stylistics, though varied, has largely been semiotically oriented. Some scholars, under the influence of Bloomfield, Hockett, and others, studied linguistic structures at the different levels of language organization (Kumar, 1977), while others linked linguistic structures to the aesthetic function (Prakasam, 1982). The work of Prakasam and his research students is largely within the Hallidayan 'systemic' model. However, a broad semiotic perspective emerged during this time that looked through language and concentrated more on the matrix of the sign, adopting both verbal and nonverbal sign systems as the axis of text production. Under the influence of Propp, Levi-Strauss, Barthes, Derrida, Benveniste, and so forth, three distinct semiotically oriented approaches were formulated on the subcontinent: Gill's 'anthropological semiotic' approach, Kelkar's 'semiosis' approach, and Srivastava's 'semiolinguistic' approach.

Gill's 'anthropological semiotic' model is motivated by the writings of the French structuralist school. He has applied his model to the analysis of legends, folk-tales, and literary works. In his *A phulkari from Bhatinda* (1981), Gill has attempted to explore the symbolic structure of Punjabi consciousness by integrating the symbolism of ritual life and the oral tradition of Punjabi folklore. He posits three distinct levels in the structuration of literary discourse: semiotics, semiology, and mediation. His first level follows the normal grammatical organization of a text, and syntactic devices of signifiers control the literary significance at this level. It is only at the plane of content that semiological significances emerge. At the second level of literary discourse, the semiological patterns are discerned through the analysis of the interplay of the psychic components of each human situation centering on a fundamental problematic or tension. The third level, mediation, emerges from the field of pragmatics, with significance coming into being from the associated field of ideology. Gill's approach is quite productive and provides fresh impetus to the study of enunciation and semantics of folklore and literary works.

Kelkar's 'semiosis' approach offers a very complex frame of reference. In his paper, 'The being of a poem' (1969), he examines, in relation to the concept of being, the capacity of a literary work to make its existence felt. In another paper, 'Some notes on language and literature' (1970), he puts forward his concept of literary style in verbal art, which for him "is the transformation of the material object (e.g., linguistic text) into the total work of art" (1970: 75). Kelkar is essentially motivated to promote the integration of linguistics, stylistics, and cultural anthropology into an overall framework of communication. In his monograph, *Prolegomena to an understanding of semiotics and culture* (published by CIIL, Mysore, in 1980), his main concern was to define, describe, and delineate semiotic events and bioethnic events by applying the formal universal approach and offering a phenomenological analysis of the forms of culture as prolegomena. In the process of evolving his complex overall framework, he has tried to integrate the world of gnosis (work, play), poesis (production, creation), and cathexis (love, loyalty).

Srivastava and his research students at the University of Delhi developed the 'semiolinguistic' approach. The semiolinguistic approach envisaged a broadening of linguistics, and at the same time a narrowing of other semiotic systems, to the pattern of linguistic signs. This approach analyzed stylistic

facts in terms of linguistic semiology by defining the nature and function of the sign, signifier, signified, and the signification process at different levels of language organization. The view promoted is that language used in literary or nonliterary discourse is a reflection on signs, and further, that language, specifically its grammars, serve as sense-making systems for all other sign systems. The semiolinguistic approach tries to show how a verbal construct with hierarchical, interlocking levels expresses the multileveled nature of a poem's signification. This is supposed to involve the principle of poetic construction as a process of semiosis that involves the transformation of one linguistic level into another, namely, the transformation of the first material level of the 'sentence symbol' into the second level of the 'symbols in art,' and further into the third level of the 'art symbol' and the 'aesthetic symbol' (see Gargesh, 1990: 57–58). The fact stressed is that all the levels and their corresponding sign-units are inherently verbal in nature. This model accepts literary communication as a social contract of the order *I – Thou* (rather than *I-It*) in its orientation. Hence, it rejects the sentence-level perspective for the study of literary texts and the formal linguistic approach that appears to suggest that there is some linguistic constant that can significantly characterize literary texts as distinct from nonliterary ones. This model has also been found practical and useful by over half a dozen research students between 1994 and 2004 through their study of style, figurative language, drama, poetry, and narrative.

It needs to be mentioned that many other scholars have also worked on the structuralist-semiotic approach in the study of various languages of India, including Marathi, Punjabi, Hindi, and so forth. Dhongde and Kelkar (1985) can be taken as a representative example. Further, efforts at establishing linkages between stylistics and the ancient Indian grammatical and critical tradition have been made by and Kapoor and Ratnam (1999).

Computational Linguistics

South Asia, particularly India, is one of the world's major software and information technology (IT) centers. A couple of decades ago, IT-related initiatives were taken in many technological institutes and universities, with funding coming from the Technology Development for Indian Languages (TDIL) program of the Ministry of Information and Technology of the Government of India. The University Grants Commission also funded many major and minor research projects. Significant achievements in the field were made by the Indian Institutes of Technology (IIT), the Indian Institute of Information Technology (IIIT), the Center for Development of Advanced Computing (C-DAC), the Indian Institute of Science, the Tata Institute of Fundamental Research (TIFR), and other universities and institutes. Researchers at the IIT at Kanpur have long been working on a project to design a machine translation system for intertranslation among major Indian languages using Sanskrit as an interlingua. They have developed a device called *Anusaaraka* that renders text from one Indian language into another in near-comprehensible form. The lexical resources being collected for Indian languages are used for the *Anusaaraka* multilingual transfer tool. Work on machine translation is also under way at the IIIT at Hyderabad. Work on Sanskrit and Hindi Corpora is going on at the Jawaharlal Nehru University and at the Mahatma Gandhi International Hindi University (MGIHU). The major thrust in this applied field can be said to be in the areas of machine translation and creating lexical resources.

Machine Translation

Major efforts in machine translation focus on translating either from one Indian language to another or on translating from English to Hindi; in Pakistan, the focus is on English and Urdu. In two *Anusaaraka* systems (Bharati *et al.*, 1995) developed in India, the load between the human readers and the machine is divided, i.e., language-based analysis of the text is carried out by the machine, and knowledge-based analysis or interpretation is left to the reader. The machine uses a dictionary and grammar rules to produce the output. *Anusaaraka* output follows the grammar of the source language. Among Indian languages, which share substantially vocabulary, grammar, pragmatics, and so forth, the task of rendering one language into another is relatively easy. However, if the two languages differ in grammatical constructions, either an existing construction in the target language that expresses the same meaning is used or a new construction is invented. *Anusaarakas* are available for use as e-mail servers.

The *Anusaaraka* system from English to Hindi follows the basic principle of information preservation. It uses the XTAG-based (Extensible Tree Adjoining Grammar) super-tagger and light dependency analyzer developed at the University of Pennsylvania for the analysis of a given English text. The system produces several outputs corresponding to the given input. The simplest possible output is based on the machine taking the load of lexicon and leaving the load of syntax to man.

Two additional systems – the *Mantra* System and the *MaTra* system – deal with machine translation

from English to Hindi. The *Mantra* system translates 'officialese' (office-related correspondence) from English to Hindi. It is based on the synchronous Tree Adjoining Grammar and uses tree transfer for translating from English to Hindi. Here, the lexicon is suitably restricted to deal with the meanings of English words as used in their subject domains. The *MaTra* system, on the other hand, is a tool for human-aided machine translation from English to Hindi for news stories. It has a text categorization component that determines the type of news (political, social, economic, and so forth) before operating on it. Depending on the type of news, the system uses the appropriate dictionary, e.g., the word 'party' is usually a 'political entity' and not a 'social event' in political news.

Lexical Resources

A number of bilingual dictionaries for Indian languages have been developed for the purpose of machine translation and are available under the GPL (General Public License). Creation of a very large English-to-Hindi lexical resource for the *Anusaaraka* system is currently under way. In Pakistan, lexical resource work is going on at the Center for Research and Urdu Language Processing at Lahore University.

Lexicon-related work in linguistics has been done by the Commission for Scientific and Technical Terminology, which is under the Ministry of Human Resource Development of the Government of India. This work is in the form of the revised Glossary of Linguistic Terms (1994) and the two-volume Definitional Dictionary of Linguistics [Vol. I (1990) deals with concepts of phonetics and phonology and Vol. II (1998) deals with concepts of morphology, syntax, and semantics]. Scholars from Delhi University, in collaboration with Iran Culture House, have created a Persian-Hindi dictionary on CD in which lexical equivalents and their grammatical forms can easily be accessed.

Language Disorders

Recent awareness of the widespread occurrence of learning disabilities (LD) in the subcontinent, both in urban and rural settings, has created another challenging area for applied linguistics in the 21st century. With the increase in data from South Asian multilingual contexts, the prevailing Western methods and materials may have to be significantly modified.

Fresh challenges lie in the area of language disorders, both developmental as well as acquired. The role of applied linguistics becomes crucial, because these disorders can be characterized at all levels of language structure and function, i.e., from articulatory and auditory speech signal-processing to problems of meaning, including all modalities of language use in production and comprehension as represented in speech and writing. The field also includes, after initial screening and diagnosis, assessment and intervention, which includes remedial teaching. Due to the large number of children going to school in South Asia, the focus at present is largely on learning disabilities rather than language disorders. This is the case for children who fail to develop age-appropriate syntax, phonology, lexicon, or pragmatics. Cross-linguistic studies related to acquired disorders (Karanth, 2003) have begun to focus on bilingualism/biscriptalism with regard to reading and with a focus on the nature of writing systems and their implications for understanding reading models. This has implications for language acquisition and language teaching as well as for the remediation of reading. Karanth has provided single case studies from the field of acquired dyslexias. All of the subjects reported were bilinguals or multilinguals who knew English and one or more Indian writing systems. The alphabetic writing system of English contrasts with the syllabic writing system of Indian languages, including the scripts of Bangladesh, Nepal, Sri Lanka, and Pakistan. Hence, the patterns of reading errors of the subjects in English, if contrasted with their reading errors in an Indian writing system, could lead to significant generalizations. The discussions of the three case studies of 'pure alexia,' 'surface dyslexia,' and 'deep dyslexia' lead to the conclusion that "in a bilingual individual a lesion that produces a particular type of dyslexia in one script need not necessarily produce a similar type of dyslexia in a different script" (Karanth, 2003: 149). The reasons include several factors related to acquisition and to the use of each language as well as the interplay between them at different stages in a bilingual's life.

It has been observed that the grapheme-phoneme correspondences that children, or even adult illiterates, make between phonology and orthography "depend on the orthography of the language being learned and the phonological units that this orthography makes salient rather than the other way round" (Karanth, 2003: 151). Further, the teaching of reading involves script-specific strategies, e.g., Indian languages are largely taught by exposure to graphemes as syllables, not as consonant and vowel components. Future studies can help create advanced remedial strategies to help children overcome their specific difficulties in spoken and written language or to help them with their attention spans in the context of traditional schools or even outside them, in literacy drives in developing countries.

In the field of learning disorders, much more work needs to be done on dyslexia, dysgraphia, and dyscalculia. Other areas that require attention from applied linguists, and are also under investigation by R C Sharma and his students at the Department of Linguistics, University of Delhi, include developmental language disorders such as those related to the communicative behavior of developmentally disabled children, language disorders in adults with aphasia and dysarthria, and dementia in the elderly.

Problems in Translation

The field of translation in the multilingual/pluricultural region of South Asia is another area of vital importance for the applied linguist. One of the cultural wings of the Government of India, the *Sahitya Akademi* (launched in 1954) has constantly promoted translation among Indian languages (and English). The *Akademi* has published over 2000 translations in 24 languages that cover the best of poetry, fiction, and drama written in the languages of India. The *Akademi* also awards each year 22 eminent translators for translating from and into an Indian language. Its journal, *Indian Literature*, now a bimonthly, has been in publication since 1957. The *Akademi* has also established four centers for translation-related activities at Bangalore, Ahmedabad, Delhi, and Shantiniketan. The center at Bangalore plans to produce translations of premodern classics in different languages of India under the series called *Prāčya*. The Sahitya Akademi holds a number of workshops for translators from different parts of the country, e.g., it has organized 19 workshops between 1999 and 2004. The aim of these workshops was to provide the translators a grounding in theoretical and practical aspects of translation so that they can meet the challenges posed by the act of translation in the context of the multilingual Indian reality. One of the dominant features of these workshops was the bringing into focus of linguistic equivalencies – lexical, syntactic, pragmatic, and cultural. Although translation is characterized as an activity whereby source language (SL) text is changed into text of the target language (TL) – while attempting to keep the meanings of the two texts equal – the fact that no two verbal systems are totally similar in representing the same sociocultural reality creates many disturbing problems for the translator in his or her efforts to maintain equivalence.

The problems of translation equivalence are varied – they may consist of untranslatable entities such as culture-specific lexicon, peculiar syntax, idioms, figurative language, and social style (see Gargesh, 1989: 63–73 for Hindi-English examples). These problems, when seen through the perspective of applied linguistics, could be resolved in the following way (Gargesh, 1989: 72):

i. Instead of performing a word-to-word translation, an attempt should be made to translate the encoded sense.
ii. In the case of poetic figures, it is advisable that an idiom for an idiom and a metaphor for a metaphor should be used, keeping in mind the sociocultural reality of the TL.
iii. Intention for intention in translation should be preferred.
iv. Transcreation is suggested, provided it doesn't embellish.

Conclusion

Language systems are central to all human behavior, and linguistics enjoys a privileged position among the sciences. Thus, it is imperative for the applied domain of linguistics to deal with issues concerning social responsibility. Applied linguistics is an interdisciplinary field where, apart from inputs from linguistics, language-related knowledge is developed and applied to language-specific practices and where language-related problems are solved in the sites of language use. Applied linguistics thus sits at the interface between linguistics and other areas of study, such as education, literary studies, literacy campaigns, media and communication studies, sociology, psychology, planning, and so forth. Issues concerning social responsibility and other related issues are frequently manifested in the areas of applied linguistics. Some of these issues have been dealt with in this article – language and education problems in a multilingual setting, problems of stylistic analysis, translation and computational linguistics, problems of linguistic changes arising out of languages in contact, psycholinguistical linguistics concerns, and so forth. Most of these issues in South Asia fall within the context of the multilingual situation. Therefore, there is a need to find out ways to make multilingualism work better so as to prevent violation of linguistic human rights and marginalization of minority languages. This effort also necessarily involves taking a critical look at the implementation and outcome of language planning and education planning so that educational structures have a firm multilingual base and output. There is also an urgent need to find effective ways of teaching languages to very large numbers of learners, which calls for harnessing and developing media-based programs via satellite. Further, fresh developments in the field need to be continuously integrated in order to make

language-related applications more realistic and intellectually stimulating.

Applied Linguistics and the Region of Southeast Asia: Definitions

For the purpose of this article, applied linguistics is defined as an interdisciplinary, practice-driven field that addresses language-related issues and problems arising in a range of real-world settings, such as the community as a whole, different educational institutions, and the workplace. To identify those relevant issues and topics in applied linguistics of significance to Southeast Asia, we examined the professional activities and the literature published in this region, not only in English but also in the local languages of the region. Much of this work has been abstracted in an extensive annotated bibliography (Ho and Wong, 2003).

Mainland Southeast Asia is taken to refer to the 10 countries that currently form a nonpolitical grouping called the Association of Southeast Asian Nations (ASEAN). They are Brunei Darussalam (henceforth

Applied Linguistics and the Region of Southeast Asia: Definitions

For the purpose of this article, applied linguistics is defined as an interdisciplinary, practice-driven field that addresses language-related issues and problems arising in a range of real-world settings, such as the community as a whole, different educational institutions, and the workplace. To identify those relevant issues and topics in applied linguistics of significance to Southeast Asia, we examined the professional activities and the literature published in this region, not only in English but also in the local languages of the region. Much of this work has been abstracted in an extensive annotated bibliography (Ho and Wong, 2003).

Mainland Southeast Asia is taken to refer to the 10 countries that currently form a nonpolitical grouping called the Association of Southeast Asian Nations (ASEAN). They are Brunei Darussalam (henceforth

Brunei), Cambodia, Indonesia, Laos, Malaysia, Myanmar, the Philippines, Singapore, Thailand, and Vietnam. Except for Thailand, all these countries experienced some form of Western colonial rule some time in the past. For example, Indonesia received its independence after four centuries of partial colonization by the Portuguese and full colonization by the Dutch. The Philippines experienced nearly as long a period of rule by Spain and then the United States. Cambodia, Laos, and Vietnam, the three states in Indochina, at one time firmly aligned with the Soviet Union, were originally French colonies. All the remaining countries, Brunei, Malaysia, Myanmar, and Singapore, were at one time colonies of the British Empire. In addition, during the Second World War, all of these countries experienced 3 years of occupation by Japan (1942–1945).

Examined closely, the countries covered in this article are vastly different in many ways – in size, for instance, with Singapore being the smallest, on the one hand, and Indonesia, on the other hand, covering thousands of islands and a total land area of approximately one quarter of the United States. Other factors making them different are, for example, their Gross Domestic Product and literacy rate. Most of the countries are heterogeneous in terms of ethnicity, culture, and language.

Southeast Asia as a Linguistic Region

The language ecology of the region comprises four 'families' of related languages, with which the national or official languages of the countries are associated. The four families, according to Comrie (1987: 12), are Austro-Asiatic (with Vietnamese and Khmer (Central Khmer) or Cambodian as its members), Tai (which includes Thai and Lao), Sino-Tibetan (which includes Chinese and Myanmar or Burmese), and Austronesian (to which Malay and Tagalog or Filipino belong). Over time, in each family, a kind of language continuum was interrupted by political boundaries.

The language mix found in Southeast Asia provides fascinating material for sociolinguistic studies. The policy of the colonial masters to impose their own languages on the colonized, together with migration of indigenous peoples across the region in search of a livelihood, has added to the complexity of Southeast Asia's linguistic profile. English remains one of two languages of instruction in the education systems of Brunei, Singapore, the Philippines, and more recently Malaysia, whereas French is taught as a second language in the Indochinese states. A good example of the diaspora of the Indian population from the early days of the British Empire is the fact that Indian languages such as Tamil, Hindi, Urdu, and Bengali are formally studied as mother tongues by some children in the Singapore education system.

Through their official language policies, in all the Southeast Asian countries, one indigenous language is accorded the status of a national language: Malay (in Brunei and Singapore), Bahasa Indonesia (in Indonesia), Bahasa Malaysia (in Malaysia), Khmer (in Cambodia), Laotian (in Laos), Filipino (in the Philippines), Thai (in Thailand), Myanmar or Burmese (in Myanmar), and Vietnamese (in Vietnam). Since Malay or a variety of it is the national or official language of Brunei, Indonesia, Malaysia, and Singapore, it is practically a *lingua franca* in the area known as the Malay Archipelago. However, at official meetings of the 10 countries as a group (ASEAN), only English is used. As will be explained, English, spoken at different levels of ability cross-nationally, is clearly the language of wider communication for the region. As a result, several countries have adopted a model of education and literacy to promote a higher level of proficiency in the English language. In the Philippines, the Bilingual Education Policy is one model, and Brunei's *Dwibahasa* (the two-language system) is another. In Singapore's bilingual education system, the medium of instruction is English. Students learn English as a first school language and the language of their ethnic group (e.g., Chinese, Malay, or Tamil) as their second school language for their cultural values.

From Nationalism to Nationism: The Adoption of National Languages

Whereas the study of language policies in this region has been a growing field of interest, the language policy literature in Southeast Asia had been rather scattered until the publication of Ho and Wong (2004a). Language policy-making involves [as Halliday (1990: 9) puts it] "formulating policies, getting them adopted and making provision – primarily educational provision – for ensuring they are carried out." It is commonly accepted that the national language is the main medium for the expression of a national identity. In all 10 Southeast Asian countries, the national and official languages are also the languages of instruction in schools. In the case of Malaysia, Indonesia, and the Philippines, there has been an institutional framework for the development and teaching of what was chosen as the national language. For most of the other countries, the agency that engages in this process is usually a department of the government or the Ministry of Education since much of language policy-making has to do with language acquisition planning. Table 1 provides a

Table 1 National languages and languages in education in Southeast Asia

Country	*National language*	*Other major languages or English as L2 or FL*	*Foreign language(s)*
Brunei	Malay	English	Arabic
Cambodia	Khmer	English	French, Chinese
Indonesia	Bahasa Indonesia	English	Arabic, Japanese, French, Dutch, German
Laos	Lao	English	French, Russian
Malaysia	Bahasa Malaysia	English, Chinese Tamil	Arabic, Japanese, French
Myanmar	Myanmar	English	
Philippines	Filipino	English	Chinese, Spanish
Singapore	Malay	English, Chinese, Malay, Tamil	Japanese, French, German
Thailand	Thai	English	French, German, Arabic, Japanese, Chinese
Vietnam	Vietnamese	English	Russian, French, Chinese

summary of the national or official and second or foreign languages of each of the 10 countries.

It is to be noted in Table 1 that each of the four countries – Brunei, Indonesia, Malaysia, and Singapore – adopted a variety of Malay as the national language. Whereas Brunei Malay predominates in that country, other varieties used in Brunei include Kampong Ayer, Royal Malay (with a social register showing respect to royalty), and Bazaar Malay (a pidginized variety). In its dual-language education system, implemented in 1984, English is used to teach some subjects in school.

In Indonesia in the early 1900s, nationalistic feelings favored the development of Malay to unite the Indonesian population, although it was not the mother tongue of the majority. Specifically, in 1928 (at the second meeting of the All-Indonesia Youth Congress), Malay was adopted as the national language (renamed Bahasa Indonesia). After the Japanese occupation (1942–1945), when independence was declared, Bahasa Indonesia was institutionalized as the official language. It has served as the medium of instruction in formal education ever since.

Among the multiethnic population of Malaysia (covering the Malay Peninsula and the states of Sarawak and Sabah in Borneo) of 19.4 million (approximately divided into 59% Malays, 32% Chinese, 8% Indians, and 1% Others), many languages and related dialects are spoken, but Malay (or Bahasa Malaysia) is the most important language, being both the national and official language, and serves as a *lingua franca*. Malaysia's language policy has moved the country from the postindependence era of establishing nationalism to one of pragmatism, in which English has been selectively used, since 2003, as one of the principal languages of instruction in schools.

In Singapore, there are four official languages: Malay, Chinese, Tamil, and English. Malay is also the national language. The composition of the Singapore population of 4 million (made up of approximately 78% Chinese, 14% Malays, 7% Indians, and 1% Others) does not reflect the actual complexity of the linguistic situation in Singapore because, in reality, the Chinese, Malays, and Indians speak a variety of languages and/or dialects. For example, among the ethnic Indians, Tamil (a major Indian language) is not necessarily the only mother tongue; there are others such as Hindi, Urdu, Gujarati, Malayalam, and Punjabi, attesting to the existence of a number of subgroups within the Indian community itself. The Chinese majority speak a mixture of Chinese dialects and, increasingly now, Mandarin. For interethnic communication, Malay (or Bazaar Malay) and English are used.

Although each of the three Indochinese states, Cambodia, Laos, and Vietnam, has its own national language, all three countries were strongly influenced by French and later Russian. In Cambodia, for instance, French was studied in public schools until the late 1960s, long after Cambodia had achieved independence.

In the remaining three countries, the national language of the Philippines is Filipino, which bears a remarkable resemblance to Tagalog. Tagalog is not the mother tongue of the largest linguistic group in the country but it met all the criteria for a national language. In the 1972 Philippine constitution, schools were charged with the responsibility of developing a "bilingual nation fully competent in the use of English and Philipino [sic]" (cited in Castillo, 2004: 268). Then, in the 1987 revision of the constitution, English and Filipino remained the official languages, but regional languages were considered official auxiliary languages in particular regions and could also serve as languages of instruction. In Myanmar with its many minority languages, Myanmar (the language) is used in administration and education. Thailand, with a population of 63.4 million and 80 languages, is not usually known as a linguistically heterogeneous society when it is so. The language that unifies Thailand is Standard Thai, which is accepted as the national and official language although, according to Brudhiprabha (1993: 16), there is no official

declaration to this effect. It is the language of education, administration, and the media and it is a symbol of identification for the Thai nation.

Given the linguistic diversity and the complexity of the language situation in Southeast Asia, any attempt at generalization must be performed with caution. What comes across very strongly is the fact that different cultural systems and historical experiences determine different linguistic profiles. In the transition from traditionalism to independence and a modern state, some countries have their own way of recognizing the legitimacy of ethnic group interests in preserving their language identity and so have made some provision for them in the school curriculum. This is a type of what Stewart (1968: 532) has called 'national multilingualism,' which exists in several countries in Southeast Asia.

The teaching of a country's national or official language(s) to eliminate illiteracy and to forge social cohesion is the most legitimate function of a country's education system. In today's fast-changing world setting, it is also expedient for the school-going population to learn another foreign or auxiliary language, such as English, if the country is to maintain contacts with the rest of the world. In the Southeast Asian setting, the fact that the national language can exist side by side with English is best seen in terms of what Fishman (1968) has called 'nationalism' and 'nationism.' In the case of nationism, English has been adopted for reasons of national efficiency.

Language Acquisition Planning in Multilingual Societies

Examples of very effective language acquisition planning through education can be observed in the region. In Malaysia, for instance, non-Malay-ethnic groups learned to master Standard Malay in a relatively short period of time. In Indonesia, Bahasa Indonesia was successfully acquired by groups who have other Indonesian languages as their mother tongues.

Perhaps the most recent success story of language acquisition planning (or language status planning) is Singapore's 'Speak Mandarin Campaign' initiated nationally for the Chinese community in 1979, in which a whole population of Chinese Singaporeans of some three generations was weaned away in approximately 10 years from dependence on Chinese dialects (technically their mother tongues) to using Mandarin (a learned language) in social interactions with family members and others. This is a major language acquisition exercise that has had no close parallel in Southeast Asia in recent times.

The success of the Speak Mandarin Campaign has put to the test notions traditionally held that language habits are slow to change. The goal of *deliberate* language change was to reduce the linguistic burden on Chinese 'dialect'-speaking children who, on introduction to formal schooling, had to learn English and Mandarin, official languages that they did not use at home. Since 1979, Mandarin has largely become an identifying characteristic of the ethnic-Chinese population instead of specific dialects. Today, the linguistically heterogeneous Chinese population in Singapore has been made more linguistically homogeneous, speaking Mandarin in intra-ethnic communication.

Language use in Multilingual Settings and the Question of Social Identity

In real-life settings, the use of many languages in different domains (workplace, home, places of worship, market-places, etc.) is now extensively documented (in particular, in Brunei, Malaysia, and Singapore) using different quantitative and qualitative methods of research. With many of these countries becoming bilingual, the question of language and identity remains a matter of concern.

How this issue of language and identity gets into public awareness has recently been demonstrated in Singapore by the study of Chinese as a school subject. To the Chinese in Singapore, the question was whether a deep knowledge of Chinese (or Mandarin) necessarily forms part of cultural identity. Although English is currently the language of interethnic communication in the social and business domains, some groups hope that English will not be cast as having value only in economic terms but also in the cultural sphere as well.

In multilingual Singapore, English probably serves as a 'focusing factor,' if we use Le Page and Tabouret-Keller's (1985: 181) concept of 'speech acts,' which are acts of projection – in which 'through language individuals project their identity, their inner universe and shape it according to the behavioral patterns of the groups with which they wish to identify.' Individuals may have several social identities. To illustrate this point, Kamwangamalu (1992), in a small-scale study, arrived at a conclusion about the relationship between language and identity in his sample, as shown in Figure 1.

Kamwangamalu's conclusion is framed by Le Page and Tabouret-Keller's (1985) ideas of 'diffusion' and 'focusing'. Under diffusion, speakers cluster based on the language that they consider their mother tongue or own language, a language that projects their own ethnic Chinese, Malay, or Indian identity, although

Figure 1 Language and identity in Singapore. Adapted from Kamwangamalu, N. (1992). 'Multilingualism and social identity in Singapore.' *Journal of Asian Pacific Communication 3*, 32–47. With kind permission from John Benjamins Publishing Company, Amsterdam/Philadelphia. http://www.benjamins.com.

they may not be proficient in that ethnic language. In other words, this diffusion, which separates the ethnic groups at one level, is seen in terms of language loyalty rather than language competence. Under focusing, English plays a supraethnic role reflecting a Singaporean identity. In other words, it is through English that speakers of it, at whatever level of competence, identify themselves as Singaporeans. As a broker language, English brings about a convergence of the different ethnic groups, hence focusing.

In Singapore and elsewhere in Southeast Asia, critics of the excessive dependence on exonormative English have expressed concern about how it may harm national identity (e.g., Tickoo, 1996: 44). Others (e.g., Denham, 1992; Samuel, 1997; Toh, 2003) note that the language pedagogy of the English textbooks shows the inappropriateness of relying too heavily on native-speaker models. With reference to the sale of English teaching materials in Vietnam, Denham (1992: 67) notes that "the USA is the top of the league in this respect, and Standard American English could eventually become the preferred model. It will be clear from these comments that Vietnam, like other Expanding Circle centres, is norm-dependent."

English: Its Expanding Role and Varieties

The expanding role of English and the varieties of English that have emerged are two issues that have often been researched and discussed in the applied linguistics literature. Held in turn in Singapore, Brunei, and Malaysia, over the past 5 years, a series of seminars under the title of *English in Southeast Asia* has been organized to discuss common concerns about emerging English varieties and the teaching of English. In Malaysia, Thailand, and the Philippines, in turn, a series of workshops provocatively entitled *English Is an Asian Language* has attempted to develop an understanding of standards in English by obtaining local responses to the acceptability of local words (in English) that grew out of their sociolinguistic and cultural environments.

In particular, policy makers and educationists in Singapore, Malaysia, the Philippines, and Brunei, as gatekeepers of language use in schools, are increasingly anxious to find out how teachers in English classrooms will be able to handle the varieties of English that have emerged in these four countries, although there is little agreement over what standard English is. Generally, as in Singapore, standard English is defined as the variety that is acceptable internationally, with reference to grammatical rules and pronunciation found in standard English (British or American) dictionaries and grammars. As one educationist in Malaysia puts it,

> If we recognize that there are varieties of Malaysian English at work in society, then we must ensure that teachers are able to handle not just the varieties of Malaysian English, but also be able to handle an internationally acceptable variety of English, too. Any teacher who has no command of a knowledge of standard English is short-changing his or her students (Gaudart, 1997: 55).

In Thailand, although a Thai variety of English exists, educationists (e.g., Prasithrathsint, 1996) accept that any discrepancy between what is standard English and the Thai variety should be attributed to the fact that English is only a foreign language in the country.

Currently, in the Southeast Asian countries where English is spoken quite extensively, a kind of diglossic situation exists, in which at least two (sub)varieties of English occur, each with a distinct range of social functions, corresponding broadly to the formal and informal/colloquial. Given this situation, a communicative strategy that is often observed in conversations in nonformal contexts in the urban areas is code-switching and/or code-mixing. In Brunei, for example, even among competent speakers of English, "when both speaker and interlocutor can also speak Brunei Malay, a great deal of code-mixing and code-switching occurs," according to Martin and Poedjosoedarmo (1996: 17). In a bilingual speech community, this happens irrespective of whether the host language is Malay, Chinese Mandarin, or Tamil, as long as the speaker and interlocutor share a common language such as English or Bazaar Malay. According to another report (Lau, 2004: 1), Malay

language experts in Malaysia are upset over the increasing number of English words entering the Malay lexicon, with popular culture "taking the cue from the government's emphasis on the importance of English."

English Language Teaching and Learning

Quite understandably, the topic of English language teaching (ELT) is the most dominant in the applied linguistics literature in this region, with a new ELT curriculum introduced in each of the 10 countries over the past 5 years. Although these countries have advocated the teaching of English from the early grades in primary school, this policy has not been fully implemented largely because of an inadequate supply of primary English teachers, in terms of both raw numbers and skill levels. To say the least, the conditions for learning English in several of the Southeast Asian countries are less than ideal, owing to underfunding, overcrowding of classrooms, a shortage or even lack of textbooks, and ill-equipped teaching areas.

Nonetheless, in most of the countries, there has been an attempt in the past 10 years to strengthen and improve the teaching of English through curriculum revision and development and other large-scale initiatives. In some of the countries, these initiatives include projects directed and funded by bilateral aid agencies such as the United Nations Development Program (UNDP). Table 2 below summarizes the more recent ELT developments in this region.

As expected, ELT objectives and targets and conditions of learning English vary among the 10 education systems. Table 3 shows that, on average, classes in Southeast Asia are large, with little opportunity for students to interact or 'communicate' in the language being learned. In most systems, the opportunity to learn and use the language is restricted by the amount of time allocated to it in the curriculum. The amount of assigned time varies from system to system, as Table 3 shows. The estimated time is distributed over a week with class duration varying from 30 to 40 minutes per class in primary schools and from 40 to 50 minutes in secondary classes. It is not possible to predict learning outcomes from the amount of time allocated alone because there are confounding variables (students' level of motivation to learn English and quality of instruction being the obvious ones).

In the past 10 years, the ELT curriculum in Southeast Asian countries appears to be driven, at least in intent, by the two concepts of 'communicative language teaching' (CLT) and 'skills integration.' CLT has become a dominant theoretical model since the 1980s in this part of the world. Translated into practical terms, the approach is usually taken to mean providing the teachers with communicative activities in their repertoire of teaching skills and giving learners the opportunity in class to practice the language skills taught. This is obviously an oversimplification but that is how CLT is generally interpreted. Most syllabuses would like to move toward CLT if conditions permit. Thailand, Indonesia, and Vietnam, to name a few countries, have set up CLT as their target for ELT. However, there is now much skepticism as to whether the kind of strategy advocated in CLT actually works in most Southeast Asian classrooms. This can be explained by a number of factors, such as teachers' inadequate command of English, poorly designed teaching materials, and the size of the typical classroom in Southeast Asian schools, which favors a particular type of teacher–pupil communication, in which the teacher asks a question and pupils respond (probably in chorus), followed by, inevitably, a comment from the teacher.

The other concept commonly adopted in the ELT curriculum is 'integration', which is linked to the idea of authenticity in CLT. The term as used in the ELT literature has several meanings but most often in ELT syllabuses, the word is used to mean integration of the four language skills. In the Singapore English Language curriculum and also in the Malaysian English syllabuses, integration of the four skills is to be carried out through a thematic approach; i.e., classroom teaching is structured across a series of language tasks in which the skills of listening, reading, speaking, and writing are used in turn. Carried out by a good teacher, the skills are not practiced in isolation, but in the hands of a poor teacher, one skill may still be taught quite independently of the others.

The issues of ELT in a number of the Southeast Asian countries may be summed up in terms of two dilemmas. On the question of supply and demand of English teachers in, for example, countries such as Thailand, Indonesia, and the Indochinese states of Cambodia, Lao PDR, and Vietnam, there is the quantitative versus qualitative dilemma. On the one hand, these countries face a dire shortage of teachers of English and, on the other, those currently teaching the language would need to improve qualitatively. So, limited resources must be distributed between recruiting and training more teachers of English and providing in-service training for those already teaching English in schools. In the area of teaching methodology in some countries, partly because of the lack of training for teachers of English, traditional practices such as text-centered grammar translation seem to remain. This is the traditional versus modern dilemma. So, although in all Southeast Asian countries

Table 2 Summary of recent developments in ELT in Southeast Asia

Country	*Recent developments*
Brunei	There has been a large-scale English language project [RELA (Reading and Language Acquisition)] to improve EL teaching and learning. Started in 1989 for lower primary, it continued in the 1990s into upper primary as Upper RELA. A new English Language Syllabus for Primary Schools was implemented in 1997 and a new series of Primary English textbooks was used in 1998. Both sets of materials incorporated features of ELT tried out and found useful in the RELA Project.
Cambodia	Since 1990, English has been officially recognized as a subject in the school curriculum. New textbooks have been developed and intensive training and retraining of English teachers provided. One such textbook was the *Cambodian English Course*, first used in 1994. It was replaced in 1997 by *English for Cambodia*.
Indonesia	English remains the most popular foreign language in Indonesian schools. Since 1995, ELT has been introduced from the fourth grade in public schools. With a reorientation of ELT objectives in the 1994 curriculum, the emphasis has been on listening and speaking skills in elementary schools and on speaking and reading skills in secondary schools.
Lao PDR	More recently, English has become the most popular foreign language in schools and at university. The emphasis of ELT is on reading, designed to help students keep abreast of developments in science and technology.
Malaysia	The English language curriculum was revised in 1993, giving emphasis to the integration of the language skills and to oracy. Further revisions were made in 2000 (for secondary schools) and 2001 (for primary schools). In the new secondary school syllabus, the emphasis is on the use of English in three areas: the interpersonal, the informational, and the aesthetic. Literature has been incorporated into the English curriculum for schools. In a dramatic change of language policy, since 2003 English has returned as a medium of instruction in schools for the teaching of science and mathematics for certain grade levels.
Myanmar	Since 1981, ELT has been introduced into all primary schools, and since 1986–1987, English has been used as a medium of instruction for science subjects and economics in schools and universities.
Philippines	ELT has moved toward the communicative, but teaching approaches remain largely eclectic. There have been several initiatives to improve the teaching of English [e.g., PELT (Philippines English Language Teaching)].
Singapore	A new English language curriculum came into effect in January 2001, the content of which is based on a model of language use, comprising language for information, language for social interaction, and language for literary response and expression. English grammar is taught more explicitly than it was in the 1991 curriculum as it is believed that students with a good knowledge of grammar should be able to use the language well in speaking and writing.
Thailand	With the National Education Act having come into force in 1997, ELT has been taught from primary one onward. There has also been a concerted effort to move away from teacher-centeredness to pupil-centeredness in ELT, and the principles of the communicative approach, although difficult to implement in Thai classes, still underpin the official thinking in ELT.
Vietnam	English language textbooks appropriate for Vietnamese learners, jointly co-authored by Vietnamese and native English speakers, have been produced. There has also been intensive training and retraining of English teachers.

Table 3 Estimates of time in school for ELT

Country	*Class size (range)*	*Time (hours)*	
		Primary	*Secondary*
Brunei[a]	40–50	3	3
Cambodia	45–60	3	4–5
Indonesia	40–50	2	3–4
Lao PDR	40–60	3–4	3–4
Malaysia[a]	38–45	4–6	3–4
Myanmar	40–60	3–5	3–5
Philippines[a]	40–60	3–4	3
Singapore[b]	35–45	4–6	4–9
Thailand	35–45	2–4	4
Vietnam	40–60	2–4	3–4

[a]English is also a medium of instruction for some school subjects.
[b]English is the medium of instruction for all subjects except the mother tongues and the subject of citizenship in primary schools.

there are strong aspirations for change and for making good progress in the teaching of English, many of the traditional conditions of teaching remain in some countries. In this sense, then, there is this unfortunate continuity between the past and the present.

The role of the Southeast Asian Ministers of Education Organization (SEAMEO) Regional Language Centre (RELC) in Singapore, in disseminating new ideas about ELT, must be acknowledged. Established in Singapore in 1968, RELC was the direct outcome of decisions made at the first meeting of the Southeast Asian Ministers of Education Council to train 'key personnel' in language education and to organize seminars on various issues of concern in the region on linguistic, psycholinguistic, sociolinguistic, and language education topics. RELC's regional (now international) seminars are widely known as important occasions, designed, among other objectives, "to exploit the results and to synthesize the efforts of an international community of scholars in related disciplines in an attempt to search for solutions to present-day language teaching and language learning problems in Southeast Asia" (SEAMEO RELC, 1977–1978).

Bilingualism in Multilingual Societies

Societal bilingualism in Southeast Asia is extremely complex even without considering the multilingual versatility of tribal minorities in the border areas of Thailand, Myanmar, and the three Indochinese states. Only two main types of societal bilingualism are outlined here. According to Tay (1985: 191), societal bilingualism may be classified according to the status of the languages, whether they are major, minor, regional, or international (or languages of wider communication). The two examples are as follows:

(a) a major language + language of wider communication (e.g., Tagalog–English; Bahasa Indonesia–English; Malay–English; and Thai–English);
(b) major language + national language + international language (e.g., Javanese/Madurese + Bahasa Indonesia + English; Mandarin + Malay + English).

The choice of an individual bilingual's repertoire in any one situation is governed by a variety of different factors: (1) the geographical area in which a language or dialect predominates, e.g., a bilingual Chinese speaker can expect to use Cantonese rather than Hokkien (two Chinese dialects) in certain towns in Malaysia because a particular town (e.g., Kuala Lumpur or Ipoh) is predominantly Cantonese-speaking; (2) domains, such as family, friendship, business transactions, employment, religion, and education. Domains may be classified along a range of formality or informality. Certain codes are typically used in certain domains; e.g., in Malaysia, Standard Malay is generally used in the more public and formal domains, whereas Bazaar Malay is used in interactions with the non-Malays in the market place. Similarly, the official languages are used in the educational domain in Singapore, but Chinese dialects continue to be used, to a lesser extent now, in family and friendship domains, especially in interactions with the elderly.

A few countries in Southeast Asia describe their education systems as bilingual, but the models of bilingual education in Singapore, Malaysia, Brunei, and the Philippines differ in many ways. Nonetheless, it is possible to argue that they are all bilingual to the extent that there are clear societal roles for the languages taught at school. Whereas Singapore and Brunei have a declared bilingual policy, the policy of Malaysia is not explicitly stated as being bilingual, although it now is for certain grade levels in schools. English has a special place in each of the four models, with the instruction time allocated to English varying from model to model. Probably, as a result of time provision and the different linguistic environments in the four countries, the outcomes of the different models have been different – Malay-dominant bilingualism for Malaysia and Brunei in the rural sector and English-dominated bilingualism in the urban areas among the non-Malay-ethnic speakers, whereas that of the Philippines may be described as Filipino-dominant bilingualism. Singapore's situation was described by Pakir (1992) as English-dominant bilingualism, although with the success of the Speak Mandarin Campaign in the past 25 years (1979–2004), there is now a greater proportion of Mandarin-dominated bilingualism. These terms for different patterns of bilingualism do not adequately recognize that the language situations in these four countries are diglossic in the sense that each major language serves different social functions.

Publications on Applied Linguistics in Southeast Asia

The field of applied linguistics in Southeast Asia is particularly active in Singapore, Indonesia, Malaysia, Brunei, and the Philippines. Each year, there are many conferences and seminars in the region, including an annual international seminar held at the RELC in Singapore, as mentioned above. There are numerous journals and reviews, such as the *RELC Journal*, *TEFLIN*, an EFL journal published in Indonesia, *ESP Malaysia*, a national journal in English for Specific Purposes, *Jurnal Persatuan Linguistik Malaysia* (*Journal of the Linguistic Association of Malaysia*, published in Malay), *Jurnal Bahasa Moden: Jurnal Fakulti Bahasa dan Linguistik Universiti Malaya* (also published in Malay), *Philippine Journal of Linguistics*, and *STETS Language and Communication Review*, published in Singapore. Journals on applied linguistics published in Chinese include *Journal of Chinese Studies, Contemporary Linguistics*, and *Linguistics and Philology*. New monographs appear on a regular basis on diverse aspects of applied linguistics, with many on different aspects of the teaching of English. Much of the substance of this article was drawn from what had been reported in these publications.

Introduction

Applied linguistics can be described as a broad interdisciplinary field of study concerned with solutions to problems or the improvement of situations involving language and its users and uses. The emphasis on application distinguishes it from the study of language in the abstract – that is, general or theoretical linguistics. However straightforward this characterization of applied linguistics may be, it is not universally embraced. In fact, ever since the term 'applied' was attached to linguistics, language specialists identifying with this field of inquiry and activity have offered and continue to offer competing, sometimes contradictory definitions and descriptions of its scope, status, and significance. Lack of consensus on an issue as basic as the domains and limits of applied linguistics poses a particular challenge to an encyclopedia compiler: how to capture the nature of a complex, dynamic field without slighting a particular point of view, a pet project, or an entire area of study?

This situation is comparable to that of many other intellectual formations that arose in the mid–20th century – such as composition studies, cultural studies, environmental studies, and women's studies – in that applied linguistics defies the traditional, taxonomic view of disciplinarity that seeks to draw clear and unambiguous boundaries. This state of affairs is addressed in the following account of how applied linguistics came about and developed as an area of study and in a survey of some issues and areas of focus that occupy those who engage in the study of language problems that affect the lives of individuals, groups of individuals, or entire societies and cultures.

Overview

One approach to understanding a field is to review the scholarly journals devoted to research on the topic. In the case of applied linguistics, which at one time had one journal – *Language Learning: A Quarterly Journal of Applied Linguistics* – published in the United States by the University of Michigan, there are several: *Applied Linguistics*, *Annual Review of Applied Linguistics*, *International Journal of Applied Linguistics*, *Journal of Applied Linguistics*, *IRAL*, *International Review of Applied Linguistics in Language Teaching*, and *AILA Review*, to name only a small sample of those with international distribution. Locally produced and distributed journals dedicated to applied linguistics are also available but to a more limited audience, for example, the *Hong Kong Journal of Applied Linguistics*, *New Zealand Studies in Applied Linguistics*, *Indian Journal of Applied Linguistics*, *ITL*, *Review of Applied Linguistics*, *Canadian Journal of Applied Linguistics*, and, from Japan, *Tsukuba Journal of Applied Linguistics*.

The *AILA Review* is the journal of the International Association for Applied Linguistics (AILA). Founded in 1964, AILA, with a worldwide membership of 8000, represents not only the disciplinary and interdisciplinary inclusiveness of the field of applied linguistics but also the geographical, linguistic, and sociocultural diversity of its practitioners and the problems they address. The inclusiveness of AILA is represented in a set of 25 topic areas called Scientific Commissions, a list that often serves as a ready-made definition of the field. Topics may emphasize learner and user groups, as in Child Language, Adult Language Learning, and Sign Language, or analytical procedures or methods, as in Contrastive Linguistics and Error Analysis, Discourse Analysis, and Rhetoric and Stylistics. Issues in information transfer and interpersonal communication are highlighted in Language and Ecology, Language and Gender, and Language and the Media. Psycholinguistics and Second Language Acquisition focus on cognitive processes. Language problems in professional contexts are associated with Forensic Linguistics, Interpreting and Translating, and Communication in the Professions, whereas other areas explicitly emphasize instructional issues: Literacy, Immersion Education, Learner Autonomy in Language Learning, Foreign Language Teaching Methodology and Teacher Education, Educational Technology and Language Learning, and Mother Tongue Education. Language Planning, Language and Education in Multilingual Settings, and Language Contact and Language Change represent research on the interplay of language use, learning, and development.

However, this list of topic areas is identified with just one applied linguistics organization and its interpretation of the field – a field that changes as problems related to language factors change. Issues in need of attention vary in intensity from time to time, or solutions are found and applied linguists move on to new challenges or return to unsolved problems using new approaches. Much depends on localized views of what applied linguistics is at a particular time, in a particular place, and in a specific set of circumstances. Three issues seem to be more enduring

and ones that applied linguists, especially those working in Western contexts, deliberate and discuss with respect to the field's identity: the relationship of applied linguistics to linguistics proper, the scope of activities in the ambit of applied linguistics, and the meaning of the term 'applied linguistics.'

Linguistics and Applied Linguistics

The role and relationship of the field of linguistics within applied linguistics has been variously interpreted in large part due to the ambiguity of the term applied linguistics. What is applied? Is it only linguistics? What is it applied to? Who is (not) an applied linguist? Is a degree in linguistics assumed? Or is it enough to be working with language-related issues? Three positions present answers to these questions.

Applied linguistics, because linguistics is part of its name, is linked to linguistics, which is sometimes referred to as the 'parent' discipline. The literal interpretation of applied linguistics as 'linguistics applied' reinforces this view. From this perspective, linguistics is the authoritative source for all that is needed to meet the aims of applied linguistics. The description of language and the concepts and terms offered by linguistic inquiry apply directly and unilaterally. The process or activity of applied linguistics is carried out by taking the known research and theory of linguistics and applying a linguistic analysis to specific contexts outside linguistics proper (e.g., language teaching, interpreting and translating, or lexicography). This position is taken by those whose work is influenced by a functional view of language in the tradition of Roman Jakobson, Michael Halliday, and Dell Hymes. This view assumes that only linguists can participate in applied linguistic work, that practitioners need credentials as linguists before they can apply known research and theory.

Another view, 'autonomous applied linguistics,' sees applied linguistics as at least semiautonomous, if not completely autonomous, from linguistics or any source discipline and allows that anyone can be an applied linguist. While acknowledging that linguistics may be part of applied linguistics, practitioners do not rely exclusively on linguistics.

A third view is known as the 'applied linguistics' position, so called because applied linguists are linguists engaged in application. It is distinguished from other views in its recognition that the knowledge and skills of a linguist are inadequate to the task of solving problems related to the uses and users of language. To address this inadequacy, the applied linguist calls upon the skills and knowledge of other professionals both inside and outside the academic world. Holders of this view more or less agree on what the field is, but the question of who can claim to be an applied linguist remains open.

Each view, regardless of the role linguistics has within it, excludes much of modern linguistics, particularly that associated with the Chomskyan approach, which deals with language at an abstract, idealized level and largely ignores language as interaction, as performance. In fact, Chomsky does not argue for the relevance of his branch of linguistics to concerns identified with applied linguistics. The linguistics that does have relevance and is of utility for applied linguists needs to be broader in aim than a search for universal grammar, and it need not be associated with any canonical school or branch of linguistics. Rather, all understanding and knowledge of language as a means of human communication is relevant and useful in solving language issues of all kinds.

Whether adopting the linguistics applied or applied linguistics view, researchers in a number of areas draw upon the theoretical and methodological approaches of sociolinguist Michael Halliday and anthropological linguist Dell Hymes. Neither sees a strict boundary between linguistics and applied linguistics, perhaps because of their distinctive approach to language studies. Halliday, first in the United Kingdom and then in Australia, developed systemic-functional linguists, whereas in the United States Hymes was key in the establishment of sociolinguistics as a legitimate discipline and in the adaptation of research techniques from anthropology into language study, namely, the ethnography of communication. Significant about both Halliday and Hymes is that neither explicitly accepted a binary distinction between general linguistics and applied linguistics. In fact, Halliday holds the view that all linguistics is sociolinguistics; that is, the study of language is the study of language in use.

Interdisciplinarity and Applied Linguistics

For some time, language teaching – first, second, and foreign – has been synonymous with applied linguistics. Since the development and improvement of classroom acquisition and competence in languages is a central educational concern for society, it is not surprising that this is one area that has long had the attention of applied linguists. This, however, was not the intention of the founders of contemporary applied linguistics, whose public and published statements on the scope of the field insisted that language teaching was but one example of the areas in which theories and methods of linguistics (in its broadest sense as the study of language) have relevance. This broader and more flexible interpretation of applied linguistics not only recognizes the limitations of relying solely on

linguistics as a source field; it also recognizes that the language problems that applied linguists address are found in many areas of human life.

Although language teaching and learning remain primary concerns in many non-Western settings, elsewhere applied linguistic activity focuses on a range of language-related issues and often draws upon other disciplines in studying language problems. Engaging expertise from other professions (e.g., medicine and law) or fields of study (e.g., psychology, communication studies, or sociology) presupposes precise identification of the problem to determine its scope. Related disciplines are tapped for available facts, techniques, and theories that can aid in addressing the problem. In some cases, there may be close collaboration with practitioners from these disciplines.

A sampling of applied linguistic studies that involve other areas of specialization includes better diagnosis of speech pathologies, design of a new orthography, natural language processing, improvements in the training of translators and interpreters, development of valid language examinations, determination of literacy levels in a population, development of tools for text analysis, comparison of the acquisition of languages from two language families or age groups, consultation to a ministry of education on introducing a new medium of instruction, developing language teaching materials, providing workplace language training, or resolving communication differences between cultural groups.

Applied linguists not only seek out the expertise of others but also can be called upon as consultants. Consulting tasks can range from advising a defense lawyer on the authenticity of the transcript of a suspect's confession to evaluating a school language program. In this, they play an indirect role in any subsequent change, improvement, or amelioration of the problem. Rather than offer any definitive solution, they provide information to help those involved in the problem solving better understand the issues, provide an explanation of what is involved, set out options for resolution, and suggest implications. The applied linguist engaged in such situations has been described as a mediator between theory and practice who enables the contribution of one to the other.

Approaches to Making Knowledge

Applied linguists take various approaches to knowledge making. Modes of inquiry vary from area to area, from researcher to researcher, and from subfield to subfield. From the 19th to the mid-20th century, the research was predominantly empirical (specifically experimental) in methodology and based on the belief that the truth about reality could be discovered through observation alone. Today, interpretive methodologies are adopted as well, either alone or, as in some subfields, in tandem, depending on the particular language-in-use problem under study. This multimodal methodology represents the integration of empiricism (qualitative as well as quantitative) and hermeneutics (interpretation and dialogue) and the recognition that no human can fully, absolutely know physical reality because of the perceptual, cognitive, and social filters that influence the ways in which a person 'sees' the physical world.

Among the approaches to research that are adopted today, the following are the most common: correlational studies with statistical methods of analysis, case study, survey by means of questionnaires or interviews, ethnography and participant–observer techniques, experimental with control and treatment groups, and, for large-scale studies, multisite multimodal approaches that rely on a variety of collection and analytical instruments and techniques. An illustration is the investigation of second language acquisition through experimental tasks and observational techniques. The former could be a pre- and post-test design to determine whether a particular linguistic feature, for example, the past tense form of irregular verbs, has been acquired (faster, longer term, more accurately or consistently, and so on) through participation in a classroom activity by the experimental group of participants. The nonexperimental methods of learner diaries or participant–observer journals could be used during the period of the study to complement pre- and post-test scores.

Although the empirical approaches and methodologies outlined previously are well represented in applied linguistics research, interpretive (or hermeneutic) methodology is also represented, although less commonly. Relevant examples are sociolinguistic studies that profile the social and linguistic features of a language of wider communication in either a second or foreign language learning context. Sociolinguistic profiles of English in a particular country (e.g., India, Germany, or Colombia) or world region (Southeast Asia, Eastern Africa, or East Asia) done by world Englishes scholars are examples of this approach. The aim is not the determination of any cause-and-effect relationships but to make general sense of the role and status of English, to understand the situations in which it is present, and, through continuing dialectic with the researcher and the participants, to achieve a new construction of the sociolinguistic situation with respect to the functions of English, of linguistic innovation and change, and of users' motivation for learning and use in diverse social and cultural contexts.

History

The origin of applied linguistics is commonly attributed to the establishment in 1941 of the English Language Institute at the University of Michigan and the coinage of the term applied linguistics to the creation in 1948 of *Language Learning: A Quarterly Journal of Applied Linguistics*. Although these developments have been influential in the institutionalization of a version of applied linguistics in the mid-20th century, both the term and the concept of applied linguistics have longer histories.

Applied Linguistics in Ancient Times

The history of applied linguistics can be traced back to the studies of grammar and rhetoric in the ancient world. A distinction between the concept of applied linguistics and the formal study of language can be found in Greece, Babylonia, and India during the fourth, third, and second millennia B.C.E., respectively, where grammarians engaged in the analysis of language as well as its practical application in the realms of teaching and text preservation (Catford, 1998). Applied linguistics in its broader definition can be found in the study of rhetoric, which examined and taught language and language production in relation to its functions in the real (i.e., not abstract) world. Evidence of rhetorical terms and concepts can be found in India from the eighth millennium B.C.E., in China between the fourth and fifth millennium B.C.E., in Greece since the fifth millennium B.C.E., and in Egypt during the early part of the second millennium B.C.E. (Kennedy, 1998).

Thinkers in these ancient civilizations, working mostly in isolation from each other, were interested in various language-related issues and their real-world implications, including the development and style of discourse, the relationship between discourse and knowledge, the construction of logical argument, the construction of credibility in discourse, the consideration of the predispositions and affective responses of the audience, and the teaching of the art of discourse production. Because they arose in close relationship with the study of knowledge and truth, early Indian, Chinese, and Greek rhetorics focused in many ways on the creation and negotiation of knowledge through discourse, resembling the social constructivist view of language in contemporary thought.

Partly because of the dominance of the Greco-Roman intellectual tradition in many areas of the world, Western rhetoric has been studied most extensively. In as early as the 5th century B.C.E., a group of scholars known as the Sophists studied forms and functions of language in various domains of life. Like their Indian and Chinese peers, Greek Sophists approached the study of language in tandem with other subjects, such as politics, law, ethics, dialectics, and many others. The rise of the concept of rhetoric as an identifiable domain of intellectual activity can be traced back to Plato, whose preference for classifying intellectual subjects into discrete units led to the denouncement of his predecessors who saw rhetoric as transcending domains of knowledge. Greek rhetoric was developed most extensively by Aristotle, whose theory of persuasive discourse in legal, ceremonial, and political domains played an important role in language education and, in recent years, influenced the development of contemporary theories of rhetoric for speech and writing instruction. Applied linguists have begun to use the Aristotelian modes of persuasion – credibility, affective, and rational appeals – as a framework for the analysis of persuasive discourse and for the development of writing tasks.

The Greco-Roman tradition of rhetoric encompassed the study of the process of discourse production including the development of ideas, organization, style, memory, and presentation as well as the teaching of the effective use of language. Although the Renaissance brought a renewed interest in classical rhetoric, the rise of modern science and the taxonomic view of disciplines between the 17th and 18th centuries stripped rhetoric of its intellectual components, relegating it largely to the study of style and figures of speech. Although rhetoric continued to be a key subject of study until the early 20th century, it focused mostly on the presentation of knowledge rather than the creation of knowledge through language.

In the 20th century, the new rhetoric movement, which is closely tied to the development of communication as well as rhetoric and composition studies, not only restored but also expanded the original scope of rhetoric. However, the influence of the broader field of rhetoric on applied linguistics has been rather limited because of the persistence of the taxonomic view of disciplinarity.

The European Origins of Early Applied Linguistics

Although applied linguistics has a long history, the term is a more recent invention, but it is older than commonly believed. The term applied linguistics, which originally arose in relation to general linguistics, can be traced back to 19th-century Europe, when linguistics was gaining recognition as an autonomous and scientific discipline distinct from philology, the humanistic study of the areas of language, culture, and literature.

One of the earliest discussions of applied linguistics took place among Indo-Europeanists during the 19th

century. Rasmus Rask, an influential Danish Indo-Europeanist and the father of comparative linguistics, made a distinction between linguistics, which is concerned with the identification of linguistic rules, and applied linguistics, which is concerned with the production of dictionaries and with the teaching of grammar (Gregersen, 1991). Catford (1998) documented the uses of the term applied linguistics or its equivalent in Russian (*prikladnoe jazykovedenie*), German (*angewandte Sprachwissenschaft*), and French (*linguistique indo-européenne appliqué*) by Indo-Europeanists such as Jan Baudouin de Courtenay, Herman Hirt, and Paul Regnaud. The goal of applied Indo-European linguistics was to apply linguistics in the realm of other sciences as well as the acquisition of first and second languages. Baudouin de Courtenay also characterized the development of the so-called international auxiliary languages – such as Johann Martin Schleyer's Volapük in 1879 and Ludovic Lazar Zamenhof's Esperanto in 1887 – as deliberate attempts to apply linguistics.

Another strand of early applied linguistics can be traced back to the Reform Movement, particularly the efforts of Henry Sweet in England, Paul Passy in France, and Otto Jespersen in Denmark. Although the Reformists did not use the term applied linguistics, Sweet made the distinction between theoretical and practical language studies: the former was concerned with the historical studies of language and etymology and the latter with language learning. Sweet saw practical language study to be on a par with theoretical study and considered phonetics to be at the core of both theoretical and practical language studies. The Reformists' principles of language teaching were summarized in *La Phonétique et ses Applications* (*Phonetics and Its Applications*), published by the International Phonetic Association (Passy, 1929). Jespersen (1928) also applied his knowledge of linguistics to the development of an international auxiliary language called Novial [the acronym for Nov (New) International Auxiliary Language].

Another significant tradition of applied linguistics that emerged in early 20th-century England is associated with the work of C. K. Ogden, who is most well-known for his collaboration with I. A. Richards in developing Basic (British American Scientific International Commercial) English. One of the central features of Basic English was the use of a limited vocabulary – an approach that was also used by Henry Sweet, Charles Fries, Michael West, and others. What is probably the first use of the term applied linguistics in English occurred in *Word Economy: A Study in Applied Linguistics* by Leonora Wilhelmina Lockhart (1931), a publication sponsored by Ogden's Orthological Institute, where Lockhart was a staff member. She sought to provide further support for Basic English by studying the efficient use of language among shorthand specialists, scientists, grammarians, creative writers, and others. Using the term applied linguistics, Lockhart described her work as an attempt to legitimize the work of applied linguists by demonstrating the practical value of language research.

Significantly, all these traditions of early applied linguistics tried to distinguish themselves from philology, and its humanistic approach to the study of language, literature, and culture, while aligning themselves with the developing discipline of 'scientific' linguistics. It is also important to note that the scope of early applied linguistics was not necessarily limited to language teaching. One of the important common applications of linguistics among these traditions during this period was the development of international auxiliary languages (Novial), which grew in popularity as the need for international communication became increasingly clear. Another common application of linguistics at the time was spelling reform. As will be shown, however, it was the pedagogical work of the Reformists – particularly that of Henry Sweet and Otto Jespersen – that became influential in the development of early applied linguistics in the United States in the 1940s.

Early Applied Linguistics in the United States

Applied linguistics in early 20th-century North America was closely tied to the rise of American structural linguistics, which continued to dissociate itself from philology. In the early 20th century, applied linguistics was seen almost exclusively as linguistics applied. Furthermore, applied linguistics was an integral part of linguistics and had no separate disciplinary identity. Linguistic descriptions were applied to the translation of the Bible into Native American languages in an effort to convert Native Americans into Christians. During the 1940s, the applied linguistic approach to language teaching played an important role in training anthropologists for fieldwork. These activities, however, were integral to the development of structural linguistics. What came to be recognized as applied linguistics took place in the contexts of language teaching – specifically the teaching of English in schools, the teaching of foreign languages other than English, and the teaching of English as a second language.

In the United States, one of the earliest deliberate attempts to apply insights from linguistics to language teaching began in the context of the teaching of English in schools. This movement was spearheaded by Fred Newton Scott, the founding president of the National Council of Teachers of English

(NCTE), and his students – most notably Sterling Andrus Leonard and Charles C. Fries. By the time NCTE was established in 1911, English classrooms in the United States – from elementary school to college – had come to be characterized by strong emphases on mechanical correctness as well as prescriptive and rigid standards of grammar based largely on British literary usage and Latin grammar. Scott and his students in the Department of Rhetoric at the University of Michigan sought to replace this prescriptive grammar with a descriptive grammar of American English based on actual usage. The efforts of Fries and others in replacing a prescriptive grammar with a descriptive grammar of English had little effect in English classrooms. In fact, Fries's sustained effort to apply structural linguistics to the teaching of English was met by strong resistance from English teachers.

The efforts to apply linguistics also took place in the teaching of foreign languages. The foremost proponent of an applied linguistic approach to foreign language teaching was Leonard Bloomfield, who was strongly influenced by the Reform Movement. Although he began developing teaching materials in the 1930s, his view was slow to gain acceptance among foreign language teachers who had emphasized the importance of reading. Bloomfield's applied linguistic approach was adopted by the American Council of Learned Societies, which needed a way of preparing anthropologists for fieldwork, and by the Army Specialized Training Program (ASTP), which sought a way of providing language instruction for military personnel during World War II. Although these programs did not last long, Bloomfield's teaching program had a significant impact on foreign language teaching in the post-World War II era, as many colleges and high schools began to develop language programs modeled after the ASTP. Furthermore, following the launch of the Russian satellite Sputnik, the U.S. government generated renewed and intense interest in expanding and improving the teaching of foreign languages (as well as mathematics) for Americans. The National Defense Education Act of 1958 promulgated the Bloomfield approach through teacher preparation programs.

The most commonly recognized tradition of early U.S. applied linguistics arose in the context of teaching English as a second language. Beginning in the mid–1930s, Fries's interest shifted from the teaching of English as a mother tongue to the teaching of English as a second language. This shift coincided with U.S. foreign policy during this period that created projects and funding opportunities in second language teaching. In 1939, at an invitational conference cosponsored by the U.S. Department of State and the Rockefeller Foundation, Charles Fries and I. A. Richards proposed competing approaches to the teaching of English to Latin American students. Fries's applied linguistics approach, drawing heavily on the work of the Reformists, was chosen over Richard's approach rooted in Basic English, which he had developed with Ogden. An outcome of this discussion was the establishment of the English Language Institute (ELI) at the University of Michigan in 1941. The ELI and its applied linguistic approach to language teaching became influential throughout the United States and even throughout the world. The Michigan ELI became influential by creating the first professional preparation program of its kind. Many of the former students and staff members – including Harold B. Allen, H. Douglas Brown, Kenneth Croft, Edward Erazmus, Diane Larsen-Freeman, Larry Selinker, William Slager, and Ronald Wardhaugh – later moved to institutions where they created or taught in graduate programs.

The Growth of Applied Linguistics

The ELI's influence was also perpetuated by many of its theoretical and pedagogical publications, including *Language Learning: A Quarterly Journal of Applied Linguistics*, the first journal known to bear the term applied linguistics as part of its title. Created in 1948 by the Research Club in Applied Linguistics at the University of Michigan, *Language Learning* has played an important role in the initial development of applied linguistics as a field of inquiry. During the first 10 years of publication, the journal expanded its readership from 200 U.S. subscribers to 1200 subscribers in 76 countries. In the 1950s, applied linguistics began to move away from linguistics because mainstream linguists were increasingly uncomfortable with the idea of language studies with implications for everyday life. By the end of the decade, applied linguists had begun to identify itself not as a branch of linguistics but in what today would be called a separate discourse community at the intersection of linguistics and language teaching (Lado, 1960).

One of the first significant events in the institutionalization of applied linguistics after the Michigan ELI and *Language Learning* was the founding in 1950 of the Annual Round Table Meeting on Linguistics and Language Teaching (which later dropped 'Language Teaching' and became the Georgetown University Round Table on Languages and Linguistics), resulting in the publication of proceedings from these meetings. Stimulated by the developments of their peers in the United States, particularly the creation of *Language Learning* and the Georgetown Round Table, Edinburgh University, Scotland, in 1956 chartered the School of Applied Linguistics, a postgraduate

program in the field, with J. C. Catford as its first director. The program later produced the *Edinburgh Course in Applied Linguistics*, a four-volume textbook series, and many of its faculty members – including S. Pit Corder, Alan Davies, Peter Strevens, and Henry Widdowson – later contributed to the development of applied linguistics throughout the world. The interest in the study of language with applications to everyday language problems grew throughout the 1950s, and the discussion of the relationship between applied linguistics and language teaching began to appear in journals such as *Modern Language Journal*.

The growing interest in applied linguistics in both the United States and Great Britain led the Ford Foundation to fund the 1957 Conference on Linguistics and the Teaching of English as a Foreign Language in Ann Arbor, Michigan. The conference, cosponsored by the Linguistic Society of America and the Conference Board of Associated Research Councils (a British organization), prompted the creation in 1959 of the Center for Applied Linguistics (CAL) with Charles Ferguson as the founding director. Initially sponsored by the Modern Language Association of America, the center was incorporated in 1964 and became an independent organization. The initial mission of CAL was to serve as an international clearinghouse for the application of linguistics in solving practical language problems, including the teaching of English. Although, with the creation of CAL, applied linguistics was beginning to broaden its scope, the teaching of English outside Britain and the United States continued to serve as a vehicle for the spread of applied linguistics in various areas of the world. For example, CAL's early activities included cosponsoring a conference on the teaching of English abroad with the United States Information Agency and the British Council, contributing to the internationalization of applied linguistics.

In 1964, the International Association of Applied Linguistics [Association Internationale de la Linguistique Appliquée (AILA)] was created as an international association of various national organizations and liaison groups for applied linguists. Its official journal, *International Review of Applied Linguistics*, was first published in 1963 and, in the following year, AILA held its first international colloquium in Nancy, France. In 1967, the British Association for Applied Linguistics came into being, and it sponsored the second AILA meeting in 1969. By this time, AILA had affiliate organizations (national associations, working groups, and centers) in 18 European and North American countries, including Austria, Belgium, Canada, Czechoslovakia, Denmark, Federal Republic of Germany, Finland, France, German Democratic Republic, Great Britain, Hungary, Italy, The Netherlands, Norway, Spain, Sweden, Switzerland, and the United States. Most of these countries were represented by a national or regional applied linguistics association, except Czechoslovakia, the German Democratic Republic, Hungary, and Switzerland, which were represented by working commissions, and Italy and the United States, which were represented by centers for applied linguistics.

As applied linguistics carved out its disciplinary niche outside of linguistics proper, it began to look to other fields, especially psychology and anthropology, for additional theoretical and methodological insights. As early as 1951, psychologist John B. Carroll (1951) explored the role of educational psychology in relation to the study and teaching of language at the second Round Table Meeting at Georgetown. In 1967, *Language Learning* officially announced its interest in publishing articles that drew on other disciplines.

The expansion of applied linguistics also meant that the language-related problem was now defined more broadly than just language teaching, encompassing first language acquisition, bilingualism, translation, sociolinguistics, psycholinguistics, writing systems, and language policy. Although the view of applied linguistics as the application of the theory of linguistics persisted, the sites of application had now expanded to include various other fields, such as geography, lexicography, medicine, and engineering as well as language teaching. The expanding scope of the field is evident in the 1969 meeting of AILA in England, which encompassed linguistic analysis of literary texts, computer analysis of texts, psychology of first language learning, psychology of second language learning, speech research, technology of language learning, language teaching materials, language teaching methodology, speech disorders and therapy, lexicography, language testing, error analysis, translation, contrastive linguistics, and sociolinguistics.

In 1973, when the editorial board of *Language Learning* considered publishing a survey of applied linguistics as a special issue, its members concluded that more than a journal issue was needed because of the broad scope of the field. Three years later, *A Survey of Applied Linguistics*, edited by Ronald Wardhaugh and H. Douglas Brown, was published. The volume covered a wide range of topics, including language development, first language teaching, orthography, reading, second language learning, second language teaching, bilingualism, dialectology, language and society, literature, language disorders, and language testing. Among other topics considered for inclusion, but omitted due to lack of space,

were translation, psycholinguistics, experimental phonetics, animal communication, extralinguistic communication, and language planning.

In the United States, Teachers of English to Speakers of Other Languages (TESOL) was created in 1966 to serve the needs of English language teaching professionals, and the publication of *TESOL Quarterly* began in the same year. In 1973, a group of applied linguists – including H. Douglas Brown, S. Pit Corder, Paul Holtzman, Robert B. Kaplan, Bernard Spolsky, Peter Strevens, Tony Robson, and G. Richard Tucker – gathered at the TESOL conference in San Juan, Puerto Rico, and began to discuss the creation of a separate organization. In the interim, the Linguistic Society of America created an applied linguistics subsection. In 1975, the constitution of TESOL was amended to allow special interest groups (SIGs), and an applied linguistics SIG (which later became the Applied Linguistics Interest Section) was created with Bernard Spolsky as its first chair. The 1977 TESOL convention in Miami sponsored a panel that explored the scope of applied linguistics, which led to the 1980 publication of *On the Scope of Applied Linguistics* edited by Robert Kaplan. Contributors were well-known and influential scholars from Great Britain and the United States – Edward M. Anthony, Thomas Buckingham, S. Pit Corder, David E. Eskey, Robert Kaplan, Stephen Krashen, John Oller, Joe Darwin Palmer, Peter Strevens, Bernard Spolsky, and Henry Widdowson – and one from South America, Francisco Gomes de Matos. In November 1977, the American Association for Applied Linguistics (AAAL) was created with Wilga Rivers as its first president.

In the same year, the Applied Linguistic Association of Australia, which had begun the publication of the *Australian Journal of Applied Linguistics* in 1976, came into being, with Ross Steele of the University of Sydney as the first president. Tim McNamara (2001) suggests that whereas U.S. and British applied linguistics in the early years tended to focus on the teaching of English to international students and to students in various areas of the world, the Australian tradition of applied linguistics, which began to arise in the 1960s, focused more on language education for its immigrant population and on foreign language education, especially French and German. Later, the emphasis shifted to the education of native English speakers and aboriginal children. In this tradition, in which linguistics was more broadly defined than in the United States, the work of linguists such as Michael Clyne and Michael Halliday continued to play an important role in applied linguistics, although other influential figures, such as Terry Quinn and Keith Horwood, brought a stronger teaching orientation to Australian applied linguistics.

As the field of applied linguistics continued to grow, the field expanded not only in its scope but also geographically. Toward the end of the 1970s and throughout the 1980s, new applied linguistics associations began to form in various areas of the World, including countries outside of continental Europe and North America. For example, the Irish Association for Applied Linguistics came into being in 1975, followed by the start up in 1978 of the Applied Linguistics Association of Korea. In 1980, the Greek Applied Linguistics Association and the Hong Kong Association for Applied Linguistics were established, and in 1982 the Japan Association for College English Teachers formed the Japan Association of Applied Linguistics. In Latin America, the Asociación Mexicana de Lingüística Aplicada and the Applied Linguistics Association of Brazil were established in 1986 and 1990, respectively. Today, AILA is a triennial congress of applied linguistic associations from throughout the world, serving applied linguistic organizations from 34 countries as well as 10 associate affiliates.

Applied Linguistics Today

The field of applied linguistics has extended in breadth and depth far beyond what anyone could imagine when the field, as it is known today, was named and recognized as an academic discipline. Researchers and scholars identifying themselves as applied linguists can be found on every continent and, as the affiliations to AILA attest, in many countries on each continent, and the number of new affiliates adds to greater international representation. Scholars in the member states of the European Union and North America, two long-standing centers of activity, are joined by colleagues in a range of global contexts.

Occupying many applied linguists in multilingual Europe are issues stemming from the development of the European Union and a pressing need for a language policy at the European level. The policy makers' goal was to respond in some equitable and practical way to the need for lingua franca communication among the member states at all levels of society and at the same time to keep other languages, particularly so-called smaller languages (spoken natively by a relatively small number of Europeans), from being devalued. This problem gains urgency with labor migration from various regions both inside and outside the European Union that adds to the multilingual mix. Thus, immigrant languages as well as the smaller

European languages (e.g., Dutch or Portuguese) or LWULTs (Less Widely Used and Lesser Taught) are the subject of investigations. Areas of focus include language attitudes, language policy, bilingual and multilingual programs and projects, teaching and learning materials, textbooks, teacher and school resources, methodological and analytical tools, and research perspectives.

Applied linguistics research is being enriched by work carried out in the Baltic States, Central and South America, the Middle East, Africa, China, South Asia, Southeast Asia, Australasia, and the Pacific region. Their contributions expand the number of new voices that document multiple sources of power in the interpretation, authentication, and representation of the concerns of applied linguistics and introduce other than Western perspectives on agendas and on feasible solutions to language-related problems.

At the regional or country level, applied linguistics is often characterized by a smaller set of specializations than presented and published at the international level. This set depends on a number of factors (e.g., urgency of language-related problems, the availability of qualified specialists, or sources of funding). A review of recent conference programs for annual meetings of the North American affiliate of AILA indicates that a large number of Canadians and Americans who attend the AAAL conference focus on second language acquisition, second/foreign language pedagogy, and discourse analysis. Members of the Russian affiliate focus on these areas as well but also have a long tradition of research in contrastive linguistics, error analysis, lexicography and lexicology – areas with a low profile, if represented at all, at the North American meeting. These differences in emphasis reveal as much about linguistic traditions as they do about the language problems that are identified as meriting consideration by applied linguistics.

Although applied linguistics in Europe and North America by and large encompasses more than language learning and teaching, many applied linguists elsewhere continue to be largely concerned with language teaching. Due to globalization of the world's economy and the attendant spread of English and its social values, considerable time, attention, and money are devoted to the teaching of English as a foreign or second language. In China, for example, although applied linguists have been engaged in activities associated with language standardization, the teaching and the computerization of the Chinese language, and the description and learning of minority languages, the teaching of foreign languages, particularly English, receives a large share of attention in current scholarship and governmental support. The recent surge in second language studies is in large part due to the modernization and economic development of China, with which English is closely associated. Reforms in English language teaching at all levels – from primary through tertiary – are a response to these social developments. The Chinese Ministry of Education has been promoting changes in teaching practice that move language teaching from a focus on intensive reading and close attention to the rules of sentence structure to the use of language for communicative purposes through spoken as well as written texts. For example, specialists in English language and teaching form the All-China Committee on the Reform of English Language Teaching at the College Level, whose charge is implementation of reforms in language teaching policies throughout China. The committee has been engaged in training teachers in new language teaching approaches and in writing textbooks reflecting advances in language teaching and language learning research that serve broad communicative goals. Regrettably, much of the research is published only in Chinese, although this is changing with postimplementation studies done outside China.

In other regions of Asia, studies investigate the challenges posed by the presence of, need for, and consequences of English, for example, in Malaysia, where the social, cultural, political, and educational challenges of English interface with Malay, also known as Bahasa Malaysia. In Korea, English language teaching's relationship to future employment prospects and financial security and parents' push for instruction at the earliest stages of schooling are prompting studies of the successes and failures of the teaching of English at all levels of education. Other topics and issues – some, but not all, relevant to Western contexts – dominate investigations, including the status of Southeast Asia as a linguistic region; adoption of national languages and the movement from nationalism to nationism (or pragmatism) in language education policy making; politics of language acquisition planning in multilingual societies; language use in multilingual settings (e.g., gatekeeping functions, code mixing and switching, and language and identity issues); the expanding role of English and the recently developed and developing varieties of English; teaching and learning of international, endangered, heritage, and less commonly taught languages; and societal bilingualism and models of formal bilingual education.

New Directions

Diverse interests and issues make up the research agenda of contemporary language-in-use research,

and it falls outside the scope of this article to discuss or describe them all. Three quite distinct directions in applied linguistic research serve to illustrate a sample of the theoretical, analytical, and ideological issues that have gained considerable attention in the past decade: critical applied linguistics, corpus analysis, and languages of wider communication.

Critical Applied Linguistics Applied linguists have been influenced by philosophical positions and intellectual activities carrying the label 'critical.' In the case of critical applied linguistics, the interest is addressing social problems involving language. Its proponents consider it an indispensable part of the intellectual activity that is applied linguistics, especially because applied linguistics claims as its mission the study of language with implications for everyday life, or the 'real world.' Critical applied linguists believe it is incumbent upon them to link language issues to general social issues (e.g., unemployment) and to be more than a student of language-related situations, namely to be an agent for social change. Generally, this is done within a broad political framework. Subsumed under this type of applied linguistics are critical literacy, critical pedagogy, and critical discourse analysis. Although this alternative approach has been the subject of a number of books, articles, and conference papers, it has yet to be widely accepted among applied linguists, many of whom are uncomfortable with the assumptions and implications of the critical position. It has, however, been widely discussed and debated, and its long-term effect on and place in the field is difficult to judge.

Corpus Analysis Corpus linguistics has been around a long time in the form of concordances used by lexicologists, lexicographers, and language syllabus designers. Its recent revival is linked to implementation of the computer in building corpora and for convenient data access. This has brought about the expansion of existing databases and the creation of new ones. A primary goal of corpus studies is identification of the linguistic characteristics and patterns associated with language use (both typical and atypical) in different contexts, for example, genres, settings, and audiences. The focus is empirical analysis, whereas the interpretation can be either qualitative or quantitative. Also new about contemporary corpus linguistics is the addition of such approaches as discourse analysis, intercultural communication, and conversational analysis to the applied linguists' tools and techniques.

Languages of Wider Communication Studies of languages of wider communication (LWC), languages that provide a mutually intelligible medium for speakers in multilingual societies, or lingua francas, are not new. However, advances in modern communication technology and travel have intensified a need for common languages. Subsequently, a variety of concerns have arisen that are relevant to areas of focus within applied linguistics, including language policy and planning, especially educational language planning; language variation and change; language teacher preparation; language and identity; and multilingualism and bilingualism. Given the role of English as a global lingua franca, it is the LWC with the lion's share of attention today. Much recent research, although not all, takes a sociolinguistic perspective and focuses on the uses and users, forms and functions, and models for learning and teaching in contexts outside of Great Britain and North America. Sociolinguistic profiles are one of the tools used to demonstrate the wide functional range, linguistic creativity, and status English has throughout the social layers of a given national or regional context. One of the more controversial aspects of this approach to the Englishes of Asia and Africa is its challenge to the ultimate authority of the native speaker. This orientation toward varieties of English is finding a place in studies of other languages of wider communication. Varieties of Spanish, both peninsular and colonial, for example, have been investigated with respect to their status among users. This is in part a response to the increased contact with, use, and learning of Spanish in the United States, conditions that make salient the choice of a variety to serve as classroom model and the status of the native speaker. The effects of the spread of languages such as English and Spanish and acknowledgment of the multiple norms their varieties provide are likely to keep applied linguists with interests in LWC engaged for some time in the solution of related language problems.

A Disciplinary Challenge

Although well represented as a discipline in established journals, book series, and conferences, consensus on a coherent theory or conceptual base for applied linguistics has not been reached. This is problematic if a goal of applied linguistics is to provide such a basis. Without a shared set of assumptions for analysis and interpretation, understanding the relationship between and among studies conducted in the various branches and subfields becomes difficult. For example, how do findings from studies in language policy relate to research in bilingual aphasia? What underlying base connects translation research to investigations of issues in second language identity?

An argument against a search for a unifying framework is that it is impossible to achieve. An applied

linguist, *per se*, does not actually exist in the sense that no one person is equally qualified or competent in the whole field. The introduction of new journals, a reflection of new areas of interest and orientation, tends to further fragment the field into specializations. This fragmentation makes it impossible to read all that is published under the rubric of applied linguistics or attend all the specialized conferences, symposia, or workshops that address these interests and specialties. The elaboration of new theoretical approaches, expansion in techniques and tools of the trade, and incorporation of an increasing number of subfields add to the challenge of defining applied linguistics as more than an umbrella term to cover a broad set of compartmentalized areas of study that are linked by a focus on language in use.

Applied Voice Input and Output Society

D Gardner-Bonneau, Portage, Michigan USA

© 2006 Elsevier Ltd. All rights reserved.

The Applied Voice Input/Output Society was established initially as the *American* Voice Input/Output Society (AVIOS) and incorporated in the state of California in the early 1980s. Its headquarters is in San Jose. Although ostensibly a nonprofit, educational, member organization from its inception, AVIOS consisted, primarily, of a Board of Directors whose main focus was the organization and execution of an annual applied speech technology conference in the United States. The AVIOS mission in the early days was education. Speech technology was new, not well-established, and its potential and limitations were not well understood by the public. The goals of the annual AVIOS conference were to educate potential users about the many and varied applications of speech technology, and to provide technical information for companies venturing into this arena and for applied researchers developing the technology itself. Early AVIOS conferences consisted of papers describing applications of speech recognition and synthetic speech in consumer products, military operations, medical environments, assistive technologies, industrial, business, and financial tasks, and aviation, for example. When Interactive Voice Response (IVR) systems entered the marketplace in the late 1980s, IVR and other telecommunications-related papers were prominently featured in AVIOS conferences over the next decade.

In accordance with its educational mission, AVIOS established the *Journal of the American Voice I/O Society* in 1984. The journal was published annually in-house from 1984 to 1990, then semiannually from 1991 to 1994. For the first ten years, Dr Gary K. Poock, from the Naval Postgraduate School, served as the Editor. In 1995, the journal was transferred to Kluwer Academic Publishers and became a quarterly, with AVIOS remaining as its sponsor. Editors since that time have been Anthony Vitale, Howard Nusbaum, and Daryle Gardner-Bonneau, who has served since 2000.

By the late 1990s, speech technology applications had become commonplace, particularly in telecommunications and financial sectors, and automatic speech recognition had been commercialized in dictation software such as Via Voice (IBM) and Dragon Naturally Speaking. Synthetic speech also was no longer novel. Because of this, the mission of AVIOS started to change from educating the public and potential users to promoting the design of new applications and the development of tools and standards that would facilitate work in the industry. Since the late 1990s, AVIOS conferences have focused more on the speech technology application developers, with sessions on technical standards, user interface design, and development tools and platforms. Because speech technology in general was becoming increasingly globalized, and because AVIOS frequently had international participation in its conferences, the organization changed the first word in its name from *American* to *Applied* at the end of the 1990s.

AVIOS has always adapted to the changing needs of the industry and, since the turn of the century, has been working to answer the call for a professional speech technology organization – a membership organization to serve the needs of developers and business professionals, as well as researchers, in the speech technology industry. Current efforts within AVIOS are to: 1) establish a strong membership base; 2) promote and facilitate the establishment of local chapter affiliates; 3) continue to develop its web presence as a source of speech technology information and services to both its members and the public; and 4) maintain and enhance the technical quality of its annual conference and its journal.

Applying Pragmatics

L F Hoye, The University of Hong Kong, Hong Kong, China

© 2006 Elsevier Ltd. All rights reserved.

The term 'applying pragmatics' (AP) is coined in this entry in preference to 'applied pragmatics' to signal that AP is a dynamic, user-oriented activity. With a wide and evolving range of applications in the societal context, AP contrasts with the somewhat fossilized term 'applied linguistics', which is primarily associated with (foreign) language learning and teaching, although it does cover linguistic applications in other areas, such as speech pathology, translation, and lexicography. Applied pragmatics embraces practices rooted in a pragmatic perspective on language users, language use, and contexts of use, where the users and their complex of personal, social, cultural, and ideational contexts are seen as paramount. If pragmatics itself is a 'user-oriented science of language', AP is a problem-solving activity with an emphasis on using pragmatic knowledge critically, imaginatively, and constructively in the real-world context of the 'social struggle', rather than on rehearsing the tenets of canonical pragmatic theory (Mey, 2001: 308–319).

The relevance of pragmatics for the wider social agenda at the micro- and macro-levels of operation can be attributed in part to a series of developmental and formative tendencies: a concerted reaction to the syntactic formalism of Chomskyan linguistics and the preoccupation with language as system, where the language user and contexts of language use are disenfranchised; a 'social-critical' impetus, fueled by the desire to create a socially sensitive practice of language, typified for instance by the work of Basil Bernstein and the critical distinction he drew between restricted and elaborated code; a unique perspective on language as action and speech act theory, initiated by the work of J. L. Austin and the work of 'ordinary language philosophers'; and a perspective on language as communication rather than on language as grammar, deriving from the ethno-methodological tradition (Mey, 1998: 716) (*see* **Codes, Elaborated and Restricted (Bernstein)**; **Austin, John Langshaw (1911–1960)**; **Ethnomethodology**).

Levels of Application: Micro- and Macro-processes

Applying pragmatics operates at both the micro- and macro-levels of communication, although this distinction is approximate and more of a labeling convenience, since the two levels interpenetrate and synergize. 'Micro-pragmatics' looks at the day-to-day context of communication between individuals and groups situated in their local contexts. At the same time, local practices need to be seen against the societal backgrounds and institutional settings in which they occur (i.e., 'macro-pragmatics'). Micro- and macro-pragmatics are points in a continuum, each linking to the other and each serving as the focus according to the aim of the enquiry. Verschueren (1999: 220–224) cites Goodwin's (1994) analysis of the Rodney King trials as a case in point. While being arrested for a traffic violation in Los Angeles, King, an African-American, was subjected to a violent beating by police officers – an event that was filmed by an amateur video photographer and later broadcast on public television to public outrage. The police officers were subsequently put on trial and later acquitted. This led to street riots in Los Angeles and a subsequent retrial. As a communicative event, the courtroom proceedings can only be properly understood in relation to the macro-setting created by the institutional and social contexts in which they took place and through which they were mediated: the particular structure and participant roles and the associated verbal processes typical of the (U.S.) courtroom and a legal/trial setting; the actual and perceived social status of African-Americans within American society, as embodied by King at the time and subsequently; and the role of community and civil rights leaders and their adoption of the King case as a heuristic to draw attention to racism and police brutality. Thus, transcriptions of the trial process can be initially approached as instances of face-to-face linguistic interaction in a courtroom setting, but as the tale unfolds, the total event and its wide-reaching implications can only be properly understood in terms of how (U.S.) legal institutions reflect, endorse, and perpetuate particular societal practices and values.

Domains of Application: Micro- and Macro-pragmatics

As a perspective rather than a component of a linguistic theory, pragmatics can purposefully be applied in the investigation of all instances of language use, whether at the level of the individual, the group, the institution, or society as a whole, and whether at the level of the sentence/utterance or in relation to extended discourse (Verschueren, 1999: 203; Mey, 1998: 728). With its focus on the sentence/utterance level of discourse, micro-pragmatics is concerned primarily with the local constraints of the immediate

context, such as: deixis and the indexing of personal, temporal, and locative features; reference and the textually directive function of anaphora and cataphora; and word order and the sequencing/clustering of particles and their discourse function to modify illocutionary force, to facilitate the management of conversation, or to highlight salient parts in a stretch of discourse (*see* **Deixis and Anaphora: Pragmatic Approaches**; **Discourse Anaphora**; **Discourse Markers**). Yet, rooted as these linguistic features are in the immediate surroundings of an utterance, the link with the world becomes apparent as the focus shifts from the individual to the wider, institutionally and societally driven contexts in which humankind must necessarily operate. To quote Mey (2001: 177):

> The world in which people live is a coherent one, in which everything hangs together: none of its phenomena can be explained in isolation.

This is now the domain of macro-pragmatics. Institutional and institutionalized language practices figure prominently on the agenda (and often), where power asymmetries may arise as the result of gender difference, perceived social standing and social privilege, and (lack of) access to power. Typical research areas and domains of application include: medical discourse and the study of language use in doctor-patient interviews, psychoanalysis, and schizophrenic discourse; educational and pedagogical language practices, such as teacher-student interaction, language acquisition and the development of pragmatic competence, the articulation of language policy in relation to minority language instruction, wording of the learning/teaching curriculum, and, more generally, the sets of attitudes and beliefs propagated through the 'hidden curriculum'; the language of the workplace and its impact on management-worker relations; the language of the media, especially advertising discourse; the language of politics, government, and ideology, viewed as a force for linguistic manipulation and the engineering of human minds; and intercultural and international communication and the (lack of) understanding of cultural and communicative diversity, where what is pragmatically appropriate in the given context is at issue. In short, macro-pragmatics considers language use in terms of the totality of contexts in which the unique, dynamic, human activity of verbal communication takes place. It takes its cues from a variety of other related disciplines, such as (linguistic) anthropology, sociology, ethnology, and linguistic science itself. (*see* **Institutional Talk**; **Media and Language: Overview**; **Language in the Workplace: Different Approaches**; **Intercultural Pragmatics and Communication**; **Language Ideology**; **Social Aspects of Pragmatics**; **Language Politics**.)

Applying Pragmatics and the Language User

Applying pragmatics aims to develop an awareness of the crucial role that language plays in the construction of individual, group, and societal identities and the consequences of these 'constructed identities' for individual freedoms and the rights of individuals to participate fully in the communities of which they are a part. Exploration of the macro-context, in relation to which all language activity takes place, is the province of 'societal pragmatics', with its unique focus on the users of language and the prevailing conditions under which they use language. Applying pragmatics highlights problems of language use that arise in social contexts where the failure to communicate successfully may lead to social exclusion and disadvantage (*see* **Social Aspects of Pragmatics**).

The domain of education is often singled out as the main sphere of human activity in which social privilege and access to power are unevenly distributed. Education is mediated and perpetuated through language. Any departure from institutionally identified standards of linguistic behavior is stigmatized and faces sanction. Hence, talk of linguistic oppression may take place, as evidenced, for instance, by the opposition between 'low' and 'high' prestige dialects. The latter can be associated with the linguistic standards whose observance is dictated for wider use by a minority but dominant class of language user. This language oppression is nothing less than social control through language. The insights provided by AP enable us to develop an awareness of the insidious effects of language repression while calling for greater transparency in how society deals with the individual's linguistic behavior in the educational setting (Mey, 1998: 731–732) (*see* **Power and Pragmatics**).

Societal pragmatics is also concerned with other social contexts in which linguistic repression is at work and where individuals behave unwittingly, in a certain way, on account of an institutionalized power imbalance. Medical discourse and the instance of schizophrenic speech are a further case in point. Schizophrenic speech is associated with abnormal language. Such speech impoverishment represents a loss of humanness, because the 'nonlanguage' of the schizophrenic, as it is now defined, has become a symptom rather than a means of communication and thus a target for psychiatric manipulation and intervention. By raising questions about the nature of interactive norms in medical practice, AP can argue the need for informed intervention, where the relationships between humanness, language use, sanity, and institutional power are placed under public scrutiny (*see* **Psychoanalysis and Language**).

Matters of linguistic diversity and endangered languages are also fertile territory for pragmatic intervention. Language attrition, language loss, and language death are all issues on the pragmatic agenda, where description is seen only as an initial step to corrective action rather than as an end in itself (*see* **Minorities and Language; Endangered Languages**). Notwithstanding controversies over the global, cultural, political, and historical impact of English on smaller indigenous languages, AP can raise public awareness, help collate data, monitor linguistic policies and practices, seek to influence policymakers, and offer practical and professional support to speech communities actively wishing to preserve their languages. For instance, the Linguistic Society of America records that active intervention in this manner, as opposed to mere description and documentation, has shown highly promising results. Its website records that:

> Language loss is [often] far more directly a consequence of intolerance for diversity [than an inevitable result of progress], particularly when practiced by the powerful against the weak.

Applying Pragmatics and the Social Struggle

Applying pragmatics is explicitly concerned with situating the concerns of societal pragmatics in terms of a broad social-political agenda; it is interventionist rather than descriptive in its primary aims. Applying pragmatics is all about doing pragmatics. As a case in point, Mey (2001: 313–315) cites the success of the linguistic war against sexism and the now mostly abandoned use of generic pronoun *he* as a modest yet significant victory for nonsexist practice. Uprooting the hegemonic *he* is not just linguistic tinkering; it brings about a restructuring of stated social relationships, thereby facilitating gender equality (*see* **Gender and Language**).

Applying pragmatics shares common concerns with critical linguistics, whose aim is to expose the hidden relationships between social power and language use, against the backdrop of sociopolitical and cultural factors. Case studies include: political discourse, specifically the clichéd rhetoric of Britain's political parties; the language of labor disputes and their documentation in the media; the use of more critically aware pedagogies in (English) second-language teaching; and the characterization of social power as a given or natural phenomenon, legitimized through unquestioning acceptance by the public (*see* **Media and Language: Overview**).

Applying pragmatics has a crucial, empowering, and emancipatory role to play. It helps us understand the power of language to discriminate indiscriminately across a range of social contexts; it suggests an agenda for pragmatically informed intervention on behalf of the disenfranchised, underprivileged language user; and, last, it seeks to put language in the hands of the language user, wresting linguistic control from those who would undermine and deny the rights and freedoms of the individual (*see* **Pragmatics: Overview; Marxist Theories of Language**).

Introduction

In this article, two senses in which it is possible to adopt a linguistic approach to translation are considered. In the first sense, the theorist adheres to something like John Catford's dictum:

> Translation is an operation performed on languages: a process of substituting a text in one language for a text in another. Clearly, then, any theory of translation must draw upon a theory of language—a general linguistic theory. [Catford, 1965: 1]

This type of linguistic approach to translation is explanatory in nature, the theorists' purpose being to account for the phenomenon of translation, and although, as the quotation from Catford makes plain, they will already have in mind a notion of what translation is (in this case 'an operation performed on languages'), it tends to be implied, if not always explicitly stated, that this application of linguistic theory is necessary for the production of a satisfactory theory of translation.

In the second sense, knowledge gained in linguistics is applied to translational phenomena, whereas the phenomenon of translation as such is theorized in its own right within the discipline known as translation studies. This is a descriptive, analytical approach, from which theoretical insights may of course very well arise, but within which the aim of applying insights from linguistics is primarily to achieve descriptive clarity.

Catford

Importance

One of the major developments in translation theory in the 20th century is Gideon Toury's (1980) reconceptualization of the notion of equivalence. Toury writes:

> Let us start our consideration of translation equivalence with a somewhat modified version of Catford's general definition (1965: 50), a modification which might be justified according to Catford's own treatment of the concept throughout his book, even if the exact formulation is not to be found in it: "Translation equivalence occurs when a SL and a TL text (or item) are relatable to (at least some of) the same relevant features". [Toury, 1980: 37]

By 'SL' and 'TL' in the quotation, Catford means 'source language' and 'target language'. The definition found in Catford (1965: 50) reads as follows (italics as in the original): "*Translation equivalence occurs when an SL and a TL text or item are relatable to (at least some of) the same features of substance*". (Catford's notion of substance will be discussed further below.) Toury (1980: 37) applies the notion of feature to "any linguistic and textual level, both in its material and functional aspects". His main addition to Catford's definition is the emphasis on relevance, of which he says (italics as in the original):

> [It] is a relative property in at least two respects: (1) it is to be regarded as an abbreviation for "relevant *for* something," or "relevant *from* a certain point of view," or the like; (2) since a text comprises various "features," on various levels (sounds, letters, syllables, morphemes, morpheme meanings, words, word meanings, compounds, meanings of compounds, syntactic patterns, sentences, sentence meanings, textual segments and principles of segmentation, etc.), all of which are – or at least may be – relevant for the totality of the text, the opposition relevant–irrelevant should be conceived of as polar, rather than binary, and we should speak in terms of *hierarchies of relevance*, rather than of absolute relevance. [Toury, 1980: 38]

When discussing translation equivalence, the relevance and selection of features (to be) shared by the two texts are central concerns. Features that are relevant when considered from the point of view of

Introduction

In this article, two senses in which it is possible to adopt a linguistic approach to translation are considered. In the first sense, the theorist adheres to something like John Catford's dictum:

> Translation is an operation performed on languages: a process of substituting a text in one language for a text in another. Clearly, then, any theory of translation must draw upon a theory of language—a general linguistic theory. [Catford, 1965: 1]

This type of linguistic approach to translation is explanatory in nature, the theorists' purpose being to account for the phenomenon of translation, and although, as the quotation from Catford makes plain, they will already have in mind a notion of what translation is (in this case 'an operation performed on languages'), it tends to be implied, if not always explicitly stated, that this application of linguistic theory is necessary for the production of a satisfactory theory of translation.

In the second sense, knowledge gained in linguistics is applied to translational phenomena, whereas the phenomenon of translation as such is theorized in its own right within the discipline known as translation studies. This is a descriptive, analytical approach, from which theoretical insights may of course very well arise, but within which the aim of applying insights from linguistics is primarily to achieve descriptive clarity.

Catford

Importance

One of the major developments in translation theory in the 20th century is Gideon Toury's (1980) reconceptualization of the notion of equivalence. Toury writes:

> Let us start our consideration of translation equivalence with a somewhat modified version of Catford's general definition (1965: 50), a modification which might be justified according to Catford's own treatment of the concept throughout his book, even if the exact formulation is not to be found in it: "Translation equivalence occurs when a SL and a TL text (or item) are relatable to (at least some of) the same relevant features". [Toury, 1980: 37]

By 'SL' and 'TL' in the quotation, Catford means 'source language' and 'target language'. The definition found in Catford (1965: 50) reads as follows (italics as in the original): "*Translation equivalence occurs when an SL and a TL text or item are relatable to (at least some of) the same features of substance*". (Catford's notion of substance will be discussed further below.) Toury (1980: 37) applies the notion of feature to "any linguistic and textual level, both in its material and functional aspects". His main addition to Catford's definition is the emphasis on relevance, of which he says (italics as in the original):

> [It] is a relative property in at least two respects: (1) it is to be regarded as an abbreviation for "relevant *for* something," or "relevant *from* a certain point of view," or the like; (2) since a text comprises various "features," on various levels (sounds, letters, syllables, morphemes, morpheme meanings, words, word meanings, compounds, meanings of compounds, syntactic patterns, sentences, sentence meanings, textual segments and principles of segmentation, etc.), all of which are – or at least may be – relevant for the totality of the text, the opposition relevant–irrelevant should be conceived of as polar, rather than binary, and we should speak in terms of *hierarchies of relevance*, rather than of absolute relevance. [Toury, 1980: 38]

When discussing translation equivalence, the relevance and selection of features (to be) shared by the two texts are central concerns. Features that are relevant when considered from the point of view of

either source text (ST) or target text (TT) may not be considered relevant from the other's point of view, and this means that what *might* constitute and what *actually* constitutes translation equivalence may also differ from the two points of view:

> From ST's point of view, translation equivalence, i.e., the "similar relevant features" which both ST and TT are "relatable to" are determined by and proportionate to their degree of relevance for ST. In its ideal form, this relationship means the reconstruction of *all* the features relevant to ST . . . which means the interchangeability (or near-interchangeability) of TT and ST. It is precisely this (near) interchangeability which is usually postulated as a necessary condition for the occurrences of translation from ST's point of view. [Toury, 1980: 38]

From the point of view of target text, in contrast, "equivalence is not a postulated requirement, but an empirical fact, like TT itself: the *actual* relationships obtaining between TT and ST" (Toury, 1980: 39; italics as in the original).

Toury calls any theory that adopts the first point of view of equivalence an ST-oriented theory. Because such a theory approaches the question of equivalence with the ideal of optimal reconstruction of ST in TT in mind as a goal, whereas actual TTs rarely manifest this ST-oriented ideal (because it tends to be far from ideal from the point of view of TT and its readership and culture), ST-oriented theories are generally very poor at accounting for actual translations; Toury argues instead for a TT-oriented approach, which (1) accepts that texts that are *viewed* as translations, in the (literary) textual systems within which they function, *are* translations, and (2) seeks to account for TT–ST relationships in terms of norms governing translation in the target culture.

This 'target text' turn in translation studies liberated the discipline from the stultification that ST-oriented theories tend to promote because of the embarrassing gap they leave between theory (translation equivalence obtains very rarely, if ever) and fact (in all cultures, texts exist that are regarded as translations and, therefore, as, in some sense, equivalent to other texts, viewed as originals). For this reason, Toury's adoption and adaption of Catford's definition of translation equivalence was crucial to the development of the discipline of translation studies in its present form, though it is important to point out that the descriptive approach, when linguistically oriented (which it need not be) is of the second type mentioned in the introduction: it applies insights from linguistics to describe phenomena that are theorized within translation studies. Few translation theorists these days would agree with Catford (1965: 19) that "the theory of translation is essentially a theory of applied linguistics"; there is a good deal more to translation theory than that.

Detail

The linguistic theory that Catford draws on is Halliday's (1961) early version of systemic functional grammar, which is outlined in the first chapter of Catford (1965). Apart from explaining "the fundamental categories of linguistic theory . . . *unit*, *structure*, *class* and *system*" (Catford, 1965: 5), Catford also explains the notion of meaning with which he (following Firth, 1957) operates: language is a type of patterned behavior in which human beings, acting interchangeably as performers and addressees, interact in social situations (1965: 1). In order to account for this behavior, the theory adopts a number of abstractions at a number of levels. First, there are the extralinguistic levels of (1) medium substance (phonic substance for speech; graphic substance for written language and, presumably, movement, in the case of signing) and (2) situation substance. Second, there are the properly linguistic levels of medium form (phonology, graphology, grammar, and lexis) and "the relationship between (the units of) grammar/lexis and situation (substance) is that of contextual meaning, or *context*" (1965: 3).

However, in addition to contextual meaning, it is necessary to consider formal meaning "which is the way any linguistic item operates in the network of formal relations" (Catford, 1965: 5); meaning as such is defined as "the total network of relations entered into by any linguistic form" (1965: 35). Because "every language is ultimately *sui generis* – its categories being defined in terms of relations holding within the language itself" (1965: 27), no two languages can realize the same formal meanings; only approximate formal correspondence can be established. Formal correspondence occurs when a category in one language occupies as nearly as possible the same place in the 'economy' of its language as a category in another language occupies in the economy of its language. Contextual meaning is similarly language specific, since the grouping of relevant situational features that a linguistic item is related to is "rarely the same in any two languages" and is, in any case, "related to formal meaning" (1965: 36). Catford provides an example from the deictic systems of North East Scottish dialect and Standard English. In the Scottish dialect, a three-term system operates (*this*, *that*, *yon*), whereas in English, there are four terms (*this*, *these*, *that*, *those*). Then (Catford, 1965: 37):

> if we assume that both systems cover approximately the same total contextual field we can represent the

contextual meanings of the constituent terms diagrammatically as follows:

	S	P		
I	this	these	this	1
			that	2
II	that	those	yon	3
	ST.E.			N.E. Sco.

The Standard English system is represented here as contextually 2-dimensional: it embodies two degrees of deixis (I, II) and two numbers (Singular, Plural). The N.E. Scots system is unidimensional, embodying only deixis – 3 degrees this time (1, 2, 3). Numerosity is a contextually irrelevant feature of situations for the N.E. Scots system.

It is clear that if we translate from Standard English to Scots we cannot 'transfer meaning'. There is no way in which, for example, Scots *that* can be said to 'mean the same' as English *that* or *this* or *these* or *those*. On a given occasion it may refer to, or be relatable to, the same feature of the situation as one of the English deictics – but its formal and contextual *meaning* is clearly different.

In view of this, it is clear that the term 'equivalent' in Catford's definition of translation cannot mean 'equivalent in meaning'. For Catford, meaning is language specific: "An SL text has an SL meaning, and a TL text has a TL meaning", and translation equivalence is grounded in interchangeability of items in situations. Since "the sentence is the grammatical unit most directly related to speech-function within a situation", then "translation equivalence can nearly always be established at sentence-rank" (Catford, 1965: 35); but even if a pair of textual items are interchangeable in a given situation, it is rarely the case that both pair members will be relatable to all of the same features of the situation. Therefore, the aim has to be the selection of items in the translation that have "the greatest possible overlap of situational range" (1965: 49) with items in the source text.

Catford sees "the bundles of situational features which are contextually relevant to a text" as "bundles of *distinctive features*" analogous to distinctive features in phonology, and even though no general theory of situation substance is available, we can say (Catford, 1965: 50; italics as in the original) that "*translation equivalence occurs when an SL and a TL text or item are relatable to (at least some of) the same features of substance*".

Nida

Importance

Whereas Catford's influence on translation studies today is undoubtedly greatest in its indirect manifestation in Toury's work (the latter being seminal to the contemporary discipline), Eugene Nida's influence has been more direct. This may result in part from the obvious relevance of his work to a ready-made audience consisting of a clearly defined and influential group of people who share his interest in Bible translating (his book, published in 1964, was dedicated to colleagues in the Translations Department of the American Bible Society), and in part from the fact that the concepts of dynamic and formal equivalence that Nida developed, although (or because) they are less carefully elaborated and theorized than any of the concepts discussed by Catford, may have more direct and easy appeal to a broad readership. Perhaps the inclusion of a chapter on 'The tradition of translation in the Western World' (Nida, 1964: chap. 2) also helps, and Nida's book is without a doubt wider in scope than Catford's. In any case, influences from Nida may be perceived in functional and cultural approaches to translation (*see* **Functional Approaches to Translation: Skopos Theory**), whereas Catford's perceived preoccupation with linguistic equivalence has tended (somewhat unthinkingly, perhaps) to be dismissed as irrelevant or at least as secondary to other considerations.

Detail

Whereas Catford sets out with a descriptivist, surface-linguistic, structuralist-oriented linguistic theory in mind, Nida declares allegiance to Chomsky's (1957, 1961) generative view of language, which "seems particularly important for a translator, for in translating from one language into another he must go beyond mere comparison of corresponding structures and attempt to describe the mechanisms by which the total message is decoded, transferred, and transformed into the structures of another language" (Nida, 1964: 9). Nida draws on this theory to develop his 'decomposition and recomposition' model of translation, comprising (1) a reduction of ST to its "structurally simplest and most semantically evident kernels", (2) transference of the meaning of these to another language, and (3) generation of "the stylistically and semantically equivalent" expressions in that language (1964: 68).

Nida is more eclectic than Catford insofar as he draws on approaches to language other than Chomsky's, in particular when discussing the concepts of meaning (which is not surprising, given Chomsky's exclusive orientation at that time to syntax). Nevertheless, Nida's main inspiration here is Katz and Fodor's (1962, 1963) attempt to add a semantics to the generative framework. Meaning, according to Nida, is a tripartite phenomenon consisting of

linguistic, referential, and emotive meaning. Linguistic and referential meaning derive from intralinguistic relationships and from relationships between these and context, and can be dealt with using a dichotomy-and-contrast-based apparatus of markers and distinguishers in the Katz and Fodor mold. Emotive meaning, however, concerns "the responses of the participants in the communicative act" (Nida, 1964: 70) and needs to be considered in terms of "polar contrasts separated by a graded series with a high percentage of usages for most words clustering around the neutral position" (1964: 113). Different selections of such series would be appropriate for different words, and the resultant matrix for each word would be highly complex.

In addition to meaning as such, a translator also needs to pay attention to what Nida referred to as "the dynamic dimension in communication" (Nida, 1964: chap. 6). His list of components of the communicative act is strongly reminiscent of Jakobson's enumeration of the factors involved in verbal communication (Jakobson, 1960: 66), comprising (Nida, 1964: 120) (1) the subject matter, (2) the participants, (3) the linguistic act, (4) the code used, and (5) the message, that is "the particular way in which the subject matter is encoded into specific symbols and arrangements". Of these components, the participants and the message are especially important, since the many different types of translation that exist can generally be accounted for by means of reference to them (Nida, 1964: 156). Messages "differ primarily in the degree to which content or form is the dominant consideration" (1964: 156), although content and form can never be completely divorced from one another. The translator's purpose may be to inform equally about content and form, but may also involve much more than information and may differ from the original author's purpose. For example, the translator may want to give the audience an insight into an alien society by producing a text closely mirroring one that was originally produced, e.g., to amuse or to guide behavior; but whatever the translator's aim, the intended audience must be considered, for "audiences differ both in decoding ability and in potential interest" (1964: 158). At this point, Nida draws a 'polar' distinction (1964: 171) between formal and dynamic equivalence (1964: 159) that has become extremely well known within translation studies, in spite of the difficulties that inhere the "principle of equivalent effect", which plays a crucial role in the distinction:

> Formal equivalence focuses attention on the message itself, in both form and content. In such a translation one is concerned with such correspondences as poetry to poetry, sentence to sentence, and concept to concept. . . . In contrast, a translation which attempts to produce a dynamic rather than a formal equivalence is based upon "the principle of equivalent effect". . . . In such a translation one is not so concerned with matching the receptor-language message with the source-language message, but . . . that the relationship between receptor and message should be substantially the same as that which existed between the original receptors and the message. [Nida, 1964: 159]

A translation that aims for formal equivalence is basically source oriented whereas a translation that aims for dynamic equivalence is oriented toward receptor response, although, as a translation, it "must clearly reflect the meaning and intent of the source" (Nida, 1964: 166). When judging translations, therefore, there are three criteria to satisfy (1964: 182): efficiency of communication, comprehension of intent, and equivalence of response. Efficiency of communication is achieved when there is maximal reception given minimal decoding effort. Comprehension of intent and equivalence of response may both be understood from the point of view of either the source or the receptor culture, depending on whether the translation (to be produced) is intended to be primarily dynamically or primarily formally equivalent to the original. However, the extent to which intent can be interpreted in a cultural context other than the one in which the message was first formulated is directly proportional to the universality of the message (1964: 182–183). The three criteria interact, since "a translation which is exceedingly literal [a formal equivalence, or F-E, translation] contains numerous awkward expressions, and is hence "overloaded" as far as the prospective receptors are concerned" (Nida, 1964: 183–184). On the other hand, "a D-E [dynamic equivalence] translation may likewise fail to come up to a valid standard, if in the translator's concern for the response of the receptors he has been unfaithful to the content of the original message". On the whole, though, Nida favors dynamic equivalence translation, since the overload that results from formal equivalence translation easily becomes so great that the translation becomes incomprehensible. The worst that can happen in dynamic equivalence translating is that translators may conceal their 'slanting' (1964: 184).

It is interesting that Nida, who set out with Chomsky's essentially psychologically, or at least intraorganism-oriented, view of language, remains largely focused on mental categories in his elucidation of translation equivalence, whereas Catford, whose starting point is more sociolinguistically oriented, remains largely focused on the relationship between text and context in his exposition of the notion.

Developments

For historical reasons, it is not possible to pursue the interesting issue of how a theory of translation that is developed on the basis of a linguistic theory might adjust to developments in the theory from which it is derived. Catford seems not to have pursued an interest in translation theory beyond 1967, at least not publicly, and translation scholars who have drawn on later versions of systemic functional grammar have used it selectively as a source of descriptive categorization or in translator pedagogy. Nida's publications subsequent to 1969 (Nida and Taber (1969) elaborate on Nida (1964)) have not maintained any obvious allegiance to Chomsky, and the latter's later output has tended not to appeal to translation studies scholars generally. More recent linguistic approaches to translation, although they are obviously not completely divorced from those of Catford and Nida (especially Nida), tend to be grounded in later linguistic theories that are only indirectly related to those of Halliday and Chomsky.

Gutt

Ernst-August Gutt's (1991) application to translation of Sperber and Wilson's (1986) relevance theory is the first and only book-length, systematic attempt to subsume translation theory within linguistics since Catford (1965), and because translation studies had by 1991 developed into a buoyant, independent discipline, the point of Gutt's effort, and its nature, differ significantly from Catford's. Whereas Catford perceived a need to account for a previously untheorized phenomenon, by 1991, several theories of or approaches to translation were available, and scholars had identified a number of theoretical concepts, concerns, and questions generally felt to be central to the discipline, or at least to subareas within it.

Gutt perceives this multiplicity of theories of and approaches to translation as a weakness and considers his own task to be to demonstrate that relevance theory is able to account for all of the phenomena perceived to be central to translation studies, and that relevance theory, therefore, is all the theory that translation studies needs (Gutt, 1991: vii–viii). Having outlined relevance theory, Gutt proceeds to measure the achievements of a number of approaches to translation against what might be accomplished by the application to the phenomena that they cover of relevance theory. He looks first at House's (1981) model for translation quality assessment and the distinction that House draws between covert and overt translation. A covert translation is one that does not reveal itself to be a translation in any way and that is generally regarded as, or as having the same status as, a first-written (original) text in the receptor culture. Covert translations alone are able to achieve functional equivalence with their source texts, and functional equivalence is House's measure of translation quality. House means by 'function' the use that a text can be put to in particular situations (House, 1981: 37), but Gutt points out that it is often very difficult to be precise about what function a particular text or text-part fulfills, and that if a translation is created in such a way that it is able to fulfill one of the source text's functions, this may mean that another function has to be forsaken. Furthermore, preservation of functionality for the receptor culture often requires radical differences at other levels, as was pointed out by, e.g., Hönig and Kussmaul (1984), who want to maintain that an advertisement that differs from its 'source' in all respects except for the preservation of the appeal function (the advertiser wants to sell a product) is nevertheless a translation of that source. This makes it difficult to distinguish translation from other forms of derived text production, whereas relevance theory would be able to account for the difference in terms of the distinction between descriptive use and interpretive use and resemblance. Descriptive use of a text occurs when the text is intended to achieve relevance in its own right (regardless of its mode of coming into existence). Translation theory need concern itself only with texts that achieve their relevance in virtue of their interpretive resemblance to other texts.

Gutt (1991: chap. 4) discusses Nida's notion of dynamic equivalence, which, as previously mentioned, is achieved when readers of a translation respond to it in the same way that readers of the original responded. In relevance theoretic terms, this means that the readers of the translation must be able to retrieve the set of assumptions that the original communicator intended to convey, and for that to be possible, they need access to the contextual information that the communicator intended the receptors of the message to use as a basis for drawing the appropriate inferences, on the basis of the interaction of the context with the discourse. Since the original context is rarely accessible to the readers of a translation, the notion of dynamic equivalence is inadequate as a measure of translational success, and Gutt (1991: chap. 5) argues that the relevance theoretic framework can provide a more satisfactory account. Relevance theory constrains translation both in terms of what it should convey and how this should be expressed:

> If we ask in what respects the intended interpretation of the translation should resemble the original, the answer is: in respects that make it adequately relevant to the audience – that is, that offer adequate contextual effects;

> if we ask how the translation should be expressed, the answer is: it should be expressed in such a manner that it yields the intended interpretation without putting the audience to unnecessary processing effort. [Gutt, 1991: 101–102]

In order to minimize processing effort, a translation should be clear and natural in expression, and in order to be optimally relevant to its audience as a text in interpretive use, it must be faithful to the original with respect to features of interest to the new audience (cf. Toury's conception of relevance as variable according to point of view). It is, however, possible to achieve these goals by way of two modes of translating, the distinction between which derives from the distinction drawn in relevance theory, between direct and indirect quotation (Gutt, 1991: chap. 6). Indirect translation focuses more on what was said than on the manner of expression, whereas direct translation focuses on the use in the translation of "communicative clues" (1991: 127) or stylistic properties that will guide the receptors of the translation to the interpretation intended by the communicator.

The task of the translator, in relevance theoretic parlance, is outlined by Gutt as follows (italics as in the original):

> The translator's responsibility begins with the formation of his informative intention ... The translator needs to clarify for himself whether his informative intention is, in fact, communicable, that is, whether he can reasonably expect the audience to derive this interpretation in consistency with the principle of relevance. Thus, the translator is confronted not only with the question of *how* he should communicate, but *what* he can reasonably expect to convey by means of his translation.
>
> The answer to this question will be determined by his view of the cognitive environment of the target audience, and it will affect some basic decisions. It will, for example, have a bearing on whether he should engage in interpretive use at all or whether descriptive use would be more appropriate ... There are instances where the fact that the information given in the receptor language text interpretively resembles an original in another language is quite irrelevant – in which case the 'translator' would simply engage in descriptive use ....
>
> In other cases the translator may judge it relevant to the audience to recognize that the receptor language text is presented in virtue of its resemblance with an original in another language. In such situations he will have to consider further what degree of resemblance he could aim for, being aware that communicability requires that the receptor language text resemble the original 'closely enough in relevant respects' (Wilson and Sperber, 1988a, p. 137). To determine what is close enough resemblance in relevant respects, the translator needs to look at both the likely benefits, that is, the contextual effects, and also at the processing effort involved for the audience. Thus he will have to choose between indirect and direct translation, and also to decide whether resemblance in linguistic properties should be included as well. [Gutt, 1991: 180–181]

Gutt's reformulation of some of the concerns of translation scholars in relevance theoretic terms has not swayed the majority away from their own preferred theoretical leanings or approaches. In particular, the shift that Gutt hoped that his book would effect (1991: 20), away from preoccupations with translational behavior and description within translation studies, has not occurred. Research has continued in the area of translational behavior, involving both 'talk aloud protocols' and other research methods, and interest in descriptive translation studies has received a significant boost with the advent of electronic means for assembling and analyzing texts (*see* **Machine Readable Corpora** and **Translation Universals**). An application of a linguistic theory to translation that takes especial account of the phenomenon of translation universals, posited by some scholars who have drawn on findings produced within this descriptivist framework, is Sandra Halverson's (2003) application of Langacker's Cognitive grammar (*see* **Cognitive Grammar**).

Halverson

Halverson describes what happens in a translation task as follows:

> In a translation task, a semantic network is activated by lexical and grammatical structures in ST [source text]. Within this activated network, which also includes nodes for TL [target language] words and grammatical structures, highly salient structures will exert a gravitational pull, resulting in an overrepresentation in translation of the specific TL lexical and grammatical structures that correspond to those salient nodes and configurations in the schematic network. [Halverson, 2003: 218]

Halverson demonstrates how the types of translation generally discussed in the literature can be explained in terms of this type of overrepresentation.

Using Data and Theoretical Insights from Linguistics in Descriptive Translation Studies

Rather than attempting to subsume translation within linguistics, it is possible to use linguistics as a source of information and descriptive clarity in studies that concentrate on the language of translated texts, perhaps in comparison with their source texts.

This type of activity is clearly different in kind from Catford's and Gutt's use of a linguistic theory to derive a theory of translation. Rather, it is an attempt to attend in an informed manner to the language of texts and translation, and this, as has been argued elsewhere (Malmkjær, 2005: 69), is a way of adopting what Scruton (1974: 145) terms the aesthetic attitude to these objects: it is a way of seeking to understand one's own (and by extension, perhaps others') reactions to them. The descriptive clarity that may be derived in this way can then be fed back into linguistics, because observing the language of translations in comparison with their source texts often provides surprising insights into both languages, which monolingual linguistic study is less likely to bring to the analyst's attention. As Goethe remarked (quotation from Gutknecht and Rölle (1996: 211)), "Wer fremde Sprachen nicht kennt, weiss nichts von seiner eigenen" (roughly, "those who don't know foreign languages know nothing of their own"), or, as Jakobson puts it, in more scholarly terms:

> Equivalence in difference is the cardinal problem of language and the pivotal concern of linguistics ... No linguistic specimen may be interpreted by the science of language without a translation of its signs into other signs of the same system or into signs of another system. Any comparison of two languages implies an examination of their mutual translatability; the widespread practice of interlingual communication, particularly translating activities, must be kept under constant scrutiny by linguistic science. [Jakobson, 1959: 233–234]

Studies in this vein can be found in Malmkjær (1993, 1995a,b, 1996, 1997, 1999, 2002).

Approaches to Translation: Relevance Theory

E-A Gutt, High Wycombe, Bucks, UK

© 2006 Elsevier Ltd. All rights reserved.

Relevance theory (RT) is a cognition-based theory of communication developed by Sperber and Wilson in the mid-1980s (Sperber and Wilson, 1986) (*see* **Relevance Theory**). It was applied to translation soon afterward (Gutt, 1988, 1991).

Main Characteristics

Following the gist of relevance theory in general, its application to translation is primarily concerned with the explanation of translation as an act of communication. It addresses two central questions: (1) What is it in the human mind that makes it possible for people to express in one language what was said in another? and (2) What are the cognitive cause-effect relations (cognitive laws) on which the success or failure of translation depends? Unlike many other approaches, this theory is not concerned with describing or classifying translated texts by types or with prescribing how translation is to be done.

The general contribution of relevance theory to translation practice may be compared to that made by one of the natural sciences, such as physics, to some field of engineering. As a better understanding of the cause-effect relations in nature can lead to improved engineering practices, so a better understanding of the cognitive cause-effect relations in communication can improve translation work. One important feature of the RT approach is its focus on what translation can or cannot achieve. This perspective may help establish a new realism in translation practice.

In essence, translation is viewed as an act of communication about another act of communication. In this way it is seen as related to quotation, with the added difficulty of crossing a language boundary. However, RT research highlights the significance of contextual differences between original and translation readership. It shows that such differences can be a second major hurdle to successful translation, one that may even outweigh language problems.

Initial Approach

In RT the term 'utterances' refers both to oral and written communication. Utterances can be used in two distinct ways: descriptively or interpretively. An utterance is used descriptively when it is intended to provide information about the state of affairs to which it refers; it is used interpretively when it is intended to provide information about the meaning of another utterance. For this intention to succeed, the new utterance has to resemble the original utterance in meaning. For further details on this distinction, see Sperber and Wilson (1995).

Following this distinction, initially relevance theorists treated translation as an instance of interpretive use based on resemblance in the semantic representations (logical forms) of the utterances (Sperber and Wilson, 1986; Wilson and Sperber, 1988). Note that the RT account of translation should not be confused with the interpretive approach of the 'Paris school' of translation (Seleskovitch, 1978; Seleskovitch and Lederer, 1984).

Translation as Interpretive Use

However, an account of translation confined to resemblance in semantic representations (logical forms) is not adequate (Gutt, 1991, 2000). First of all, interpretive resemblance between utterances needs to be defined not in terms of their semantic representations (logical forms) but in terms of their interpretations.

Approaches to Translation: Relevance Theory

E-A Gutt, High Wycombe, Bucks, UK

Relevance theory (RT) is a cognition-based theory of communication developed by Sperber and Wilson in the mid-1980s (Sperber and Wilson, 1986) (*see* **Relevance Theory**). It was applied to translation soon afterward (Gutt, 1988, 1991).

Main Characteristics

Following the gist of relevance theory in general, its application to translation is primarily concerned with the explanation of translation as an act of communication. It addresses two central questions: (1) What is it in the human mind that makes it possible for people to express in one language what was said in another? and (2) What are the cognitive cause-effect relations (cognitive laws) on which the success or failure of translation depends? Unlike many other approaches, this theory is not concerned with describing or classifying translated texts by types or with prescribing how translation is to be done.

The general contribution of relevance theory to translation practice may be compared to that made by one of the natural sciences, such as physics, to some field of engineering. As a better understanding of the cause-effect relations in nature can lead to improved engineering practices, so a better understanding of the cognitive cause-effect relations in communication can improve translation work. One important feature of the RT approach is its focus on what translation can or cannot achieve. This perspective may help establish a new realism in translation practice.

In essence, translation is viewed as an act of communication about another act of communication. In this way it is seen as related to quotation, with the added difficulty of crossing a language boundary. However, RT research highlights the significance of contextual differences between original and translation readership. It shows that such differences can be a second major hurdle to successful translation, one that may even outweigh language problems.

Initial Approach

In RT the term 'utterances' refers both to oral and written communication. Utterances can be used in two distinct ways: descriptively or interpretively. An utterance is used descriptively when it is intended to provide information about the state of affairs to which it refers; it is used interpretively when it is intended to provide information about the meaning of another utterance. For this intention to succeed, the new utterance has to resemble the original utterance in meaning. For further details on this distinction, see Sperber and Wilson (1995).

Following this distinction, initially relevance theorists treated translation as an instance of interpretive use based on resemblance in the semantic representations (logical forms) of the utterances (Sperber and Wilson, 1986; Wilson and Sperber, 1988). Note that the RT account of translation should not be confused with the interpretive approach of the 'Paris school' of translation (Seleskovitch, 1978; Seleskovitch and Lederer, 1984).

Translation as Interpretive Use

However, an account of translation confined to resemblance in semantic representations (logical forms) is not adequate (Gutt, 1991, 2000). First of all, interpretive resemblance between utterances needs to be defined not in terms of their semantic representations (logical forms) but in terms of their interpretations.

The interpretation of an utterance consists of the set of thoughts (RT: assumptions) it is intended to convey. Two interpretations resemble each other to the extent that they contain the same assumptions. Thus, interpretive resemblance between utterances forms a continuum ranging from no resemblance (= no assumptions shared) to complete interpretive resemblance (= all assumptions shared). Applying these insights to translation, then, translations are acts of the interlingual interpretive use of utterances based on the resemblance of their interpretations.

Using the maximal end-point of the resemblance continuum – complete interpretive resemblance – the notion 'direct translation' can be defined along the following lines. In intralingual communication, one of the unique features of direct quotation is that it allows, at least in principle, the full recovery of the originally intended interpretation – provided it is processed in the originally intended context. This crucial condition follows from the cause-effect interdependence of stimulus, intended interpretation, and context, due to the inferential nature of communication (Sperber and Wilson, 1986; Gutt, 1991).

Applied to cross-language situations, one can define a mode of interlingual communication that aims to convey the same intended interpretation as the original text – again with the crucial proviso that it is processed using the same contextual information as the original. This mode is called 'direct translation' (Gutt, 1991). Because contextual information is rarely ever exactly the same between two individuals, direct translation is better characterized in terms of a dependency relationship: The closer the context of a direct translation resembles that of the original, the closer its interpretation will resemble the original interpretation.

The demand that translations should convey the same meaning as the original (= achieve complete interpretive resemblance) has, of course, been voiced for centuries. The significance of the notion of 'direct translation' is the realization that the achievement of this goal depends a great deal on the use of the originally intended contextual information. To expect a translated text to communicate accurately the intended meaning of the original in a context significantly different from the original one goes against the basic laws by which communication works and is therefore unrealistic. This insight entails that readers of translations who are interested in getting as close to the meaning of the original as possible must familiarize themselves with the original context (Gutt, 1991). This is not an option, but a necessity conditioned by the cognitive laws of communication.

Regarding language differences, the achievement of interpretive resemblance in translation depends not so much on the sharing of concrete linguistic properties as on the possibility of replicating in the target language the more abstract communicative clues provided by those properties (Gutt, 1991). For example, the source language may have a special morpheme to indicate the heightened relevance of a text section; even though the target language may lack such a morpheme, other means, perhaps a combination of lexical and structural features, may have the same effect on the interpretation. In such cases, the translation would yield the same interpretation as the original – if processed with the original contextual information – by providing the same communicative clues, despite the linguistic differences.

Although the possibility of matching communicative clues is not generally guaranteed, the mode of direct translation does offer the highest possible degree of interpretive resemblance to the original, depending on how closely the context used resembles that of the original.

Any translation aiming at lower degrees of interpretive resemblance falls under the mode of 'indirect translation' (Gutt, 1991). Indirect translation does not require readers to familiarize themselves with the original context; in fact, it typically uses the current context of the target audience. This feature gives indirect translation the advantage of high spontaneous comprehensibility.

Significantly, according to the cognitive laws of communication, the nature of that particular context determines the degree to which its meaning can resemble that of the original. This explains why the popular demand that translations should give the full meaning of the original and be easily comprehensible cannot be fulfilled in situations where the context of the translation differs significantly from that of the original.

Thus, here is the answer to the question raised at the beginning of this article about the cognitive laws that determine the success of translation: The possibilities and limitations of translation are very much determined by the general human comprehension procedure, with its causal interaction of meaning, stimulus, and context. This highlights in a new way the crucial role that context plays in translation, quite apart from language differences.

The answer to the other question raised above – what characteristic of the human mind makes translation possible? – is that the phenomenon of translation can be explained in terms of the interaction of the general ability to communicate (as spelled out in relevance theory) and the language faculty. Taken

together, these two answers suggest that, from the cognitive point of view, no special theory of translation is needed, neither to explain the human ability to translate nor the success and failure of translations to communicate (Gutt, 1991).

This approach also explains the inconclusiveness of numerous attempts to define clearly the difference between translation and paraphrase, between literal and free translation, and the like in terms of the similarities or differences between original and target text. Interpretive resemblance being a continuum, it offers no nonarbitrary points for such demarcations.

In some cases, texts are based on information found in texts in some other language without, however, any intention of informing the target readership about those other texts. Examples are tourist brochures, instruction manuals, and advertisements. Traditionally, such texts have been dealt with by translation theory ('covert translations'; House, 1981). Yet, what ultimately accounts for the success or failure of such texts is not how closely they resemble the original, but whether the information they provide is correct and/or effective. Thus, they turn out to be instances of interlingual descriptive use and are quite different from translation (Gutt, 1991).

Criticisms

The RT approach to translation has found considerable attention worldwide (for a list of reviews, see Gutt, 2000). Responses have ranged from severe criticism to approval, application, and further development of the approach.

One major criticism is directed against the claim that no distinct theory of translation is required (Tirkkonen-Condit, 1992). This objection reflects, however, a failure to distinguish between two quite different notions of theory: explanatory theory on the one hand, which is concerned with the understanding of cause-effect relations in a particular domain, and descriptive theory on the other, which aims at the systematic description of phenomena seen as related in some way. The obsoleteness of a distinct translation theory is asserted with regard to cognitive explanation not with regard to the systematic compilation of knowledge about translation (see Gutt, 2000).

The lack of concrete translation rules and guidelines has been another source of criticism (Malmkjaer, 1992). It is not that these concrete rules are without value, but that their value is seriously limited. In essence, they are particular applications of the general laws of communication. Yet, because their limitations are rarely spelled out, they often fail to provide reliable guidance (Savory, 1957). Furthermore, they do not provide help to the translator for any problems they do not address. Understanding the basic laws of communication prepares translators for all situations and is therefore more helpful in the long term (for a further discussion of this issue, see Gutt, 2000).

The treatment of 'covert translation' as interlingual descriptive use rather than as translation proper has also been criticized (Chesterman, 2002). Yet, on the theoretical side, treating 'covert translation' as 'translation' obscures their fundamentally different nature. On the practical side, it tends to conceal that target language originals would often be much more effective than covertly translated texts. The translational approach is often used simply as a matter of convenience or cost reduction (for further discussion, see Gutt, 2000).

The neglect of the notion 'skopos' introduced by Reiss and Vermeer (1984) – that is, of the purpose for which a translation is made – has also come under criticism (Hatim, 1998). The RT response to this is twofold. First, the notion 'skopos' has largely arisen from the need to explain the often radical differences between original and target language texts occurring in covert translation. Because covert translations function as originals in their own right, 'skopos' is not needed to explain them as cases of translation. Second in translation proper (interlingual interpretive use), the success or failure of translated texts is already accounted for by the degree to which the intentions of the translator and the expectations of the target audience match up (Gutt, 1991, 2000).

Further Developments

Later developments in relevance theory have generalized the notion of 'interpretive use' by introducing the concept of 'metarepresentation' (Noh, 2000; Sperber, 2000; Wilson, 2000). Like interpretive use, metarepresentation occurs when one representation is used to represent another; for example, when quoting someone. In contrast to interpretive use, the two representations do not have to resemble each other in their meaning, but can share their formal linguistic properties – metalinguistic resemblance (Wilson, 2000). Wilson argued that metarepresentation captures all instances of "representation by resemblance," thus "leaving the way open to a unified account" (Wilson, 2000: 425).

Translation as Metarepresenational Use

Applying these insights, Almazán Garcia (2002: 175) reanalyzed the notion of translation as metarepresentational use: "Translation is an instance of the metarepresentational use of utterances where the metarepresented and the metarepresenting utterances

happen to be in different languages." This analysis naturally included a group of translation phenomena that had to be treated as exceptions, because they were based on similarities in linguistic structure, rather than on intended meaning (Gutt, 1991). Interlinear morpheme-by-morpheme translations are a case in point. Almazán Garcia (2002) also claimed that this approach had no need for the concept of "communicative clue".

Translation as a Higher-Order Act of Communication

Yet, utterances can be seen as ostensive stimuli, not representations (Gutt, 2005). The main reason for this approach is that mental representations inherently represent, but utterances do not. In fact, utterances 'represent' (= have representational content) only via their association with mental representations (Carston, 2002). If utterances do not represent, communication relying on formal linguistic resemblances between them does not fall under metarepresentational use.

Therefore, acts of communication about other acts of communication are not metarepresentations, but rather higher-order acts of communication (HOACs). Any such act can aim to provide information about either of the two key elements of the original communication: the stimulus used or the interpretation intended. HOACs that focus on the stimulus are said to be in 's-mode' (stimulus-oriented mode). They inform the target audience of the utterance used. Those focusing on the intended interpretation are said to be in 'i-mode' (interpretation-oriented mode); they inform the audience of what the utterance meant.

I-mode HOACs correspond very closely to the interpretive use of utterances. However, the concept 's-mode HOAC' is much more general in its coverage than the concept 'linguistic metarepresentation'. It is not restricted to resemblance in linguistic properties (metalinguistic resemblance), but applies to resemblance in any perceptible features. It therefore also naturally extends to nonverbal HOACs, currently not included in the metarepresentational framework.

Applied to cross-language communication, an i-mode HOAC corresponds quite straightforwardly to indirect translation. An s-mode HOAC covers all cases involving metalinguistic resemblance, as well as cases involving the sharing of properties other than linguistic ones.

Interestingly, direct translation turns out to be of a very special nature. As pointed out above, interlingually, complete interpretive resemblance (in the original context) requires the sharing not of the concrete properties of the original utterance but of its communicative clues. Communicative clues are, on the one hand, dependent on the properties of the original and on its intended interpretation, on the other hand. Thus, direct translation might be considered a sophisticated hybrid of s- and i-modes. This analysis might go a long way toward explaining why producing an authentic translation is such a challenging task, usually requiring special training. Work on this approach is still in progress.

Bibliography

A concise introduction to the interpretive–use account of translation is found in Gutt (1992), a more comprehensive treatment in Gutt (2000), with responses to peer comments in its 'Postscript' chapter. Hill (2002) is of interest as a more extensive application of the relevance-theoretic approach to translation involving experimental testing. Setton (1998) utilizes some notions of relevance theory for a theory of simultaneous interpretation.

Introduction

The term 'apraxia' refers to a distinct category of acquired central nervous system disorders that are characterized by an inability to carry out symbolic or purposeful motor actions, despite the absence of primary sensory or motor deficits.

The first use of the word 'apraxia' is attributed to the German philosopher and psychologist Heymann Steinthal (1823–1899), who used the term in an 1871 publication, but the behavioral phenomenon may have been described by the 'father' of British neurology, John Hughlings-Jackson (1835–1911), about five years earlier. He noted that some patients with aphasia were unable to perform certain types of voluntary movements to command, such as coughing or protruding their tongue, even though there was no evidence of weakness or paralysis. Moreover, patients could easily protrude their tongue spontaneously, as part of for example licking their lips after drinking.

The first systematic clinical studies of patients with apraxia were performed by Hugo Karl Liepman (1863–1925), a student of Carl Wernicke. He published his first case description of a 48-year-old man with unilateral apraxia in 1900. Liepman's theories were well received, but had relatively little impact on the scientific community until revived by the behavioral neurologist Norman Geschwind (1926–1984). In his article 'Disconnexion syndromes in animals and man' published in 1965, Geschwind described apraxia and other neurological syndromes that he hypothesized could be explained on the basis of an interruption of specific white matter pathways that interconnect different regions of the brain (Geschwind, 1965). The verbal instruction for a motor command is first processed in Wernicke's area in the posterior superior temporal lobe. The information is then relayed to the ipsilateral motor association cortex, most likely via the arcuate fasciculus. Performance of movements with the right hand is made possible when the information reaches the left primary motor cortex. In order to perform a movement command with the left hand, the additional step of transferring the information via the corpus callosum to the right motor association and primary motor cortex is required. Geschwind's theoretical account of apraxia thus had many similarities with that proposed by Carl Wernicke to explain various syndromes of aphasia.

Definition

Strictly speaking, apraxia means 'no action.' Geschwind defined apraxia as an acquired impairment in the execution of purposeful, learned movements in the absence of weakness, inattentiveness, or lack of cooperation. The term has also sometimes been used to describe unexplained clumsiness or lack of coordination, as in 'gait apraxia.' 'Apraxia of speech' is sometimes used to describe nonarticulatory abnormalities of phoneme sequencing (paraphasias) that are common in patients with conduction aphasia as well as other aphasia syndromes. Apraxic agraphia is a condition in which the patient has difficulty with the actual formation of letters, in the absence of difficulties with spelling or grammar. Patients with apraxic agraphia can therefore type or use a word processor without difficulty.

Introduction

The term 'apraxia' refers to a distinct category of acquired central nervous system disorders that are characterized by an inability to carry out symbolic or purposeful motor actions, despite the absence of primary sensory or motor deficits.

The first use of the word 'apraxia' is attributed to the German philosopher and psychologist Heymann Steinthal (1823–1899), who used the term in an 1871 publication, but the behavioral phenomenon may have been described by the 'father' of British neurology, John Hughlings-Jackson (1835–1911), about five years earlier. He noted that some patients with aphasia were unable to perform certain types of voluntary movements to command, such as coughing or protruding their tongue, even though there was no evidence of weakness or paralysis. Moreover, patients could easily protrude their tongue spontaneously, as part of for example licking their lips after drinking.

The first systematic clinical studies of patients with apraxia were performed by Hugo Karl Liepman (1863–1925), a student of Carl Wernicke. He published his first case description of a 48-year-old man with unilateral apraxia in 1900. Liepman's theories were well received, but had relatively little impact on the scientific community until revived by the behavioral neurologist Norman Geschwind (1926–1984). In his article 'Disconnexion syndromes in animals and man' published in 1965, Geschwind described apraxia and other neurological syndromes that he hypothesized could be explained on the basis of an interruption of specific white matter pathways that interconnect different regions of the brain (Geschwind, 1965). The verbal instruction for a motor command is first processed in Wernicke's area in the posterior superior temporal lobe. The information is then relayed to the ipsilateral motor association cortex, most likely via the arcuate fasciculus. Performance of movements with the right hand is made possible when the information reaches the left primary motor cortex. In order to perform a movement command with the left hand, the additional step of transferring the information via the corpus callosum to the right motor association and primary motor cortex is required. Geschwind's theoretical account of apraxia thus had many similarities with that proposed by Carl Wernicke to explain various syndromes of aphasia.

Definition

Strictly speaking, apraxia means 'no action.' Geschwind defined apraxia as an acquired impairment in the execution of purposeful, learned movements in the absence of weakness, inattentiveness, or lack of cooperation. The term has also sometimes been used to describe unexplained clumsiness or lack of coordination, as in 'gait apraxia.' 'Apraxia of speech' is sometimes used to describe nonarticulatory abnormalities of phoneme sequencing (paraphasias) that are common in patients with conduction aphasia as well as other aphasia syndromes. Apraxic agraphia is a condition in which the patient has difficulty with the actual formation of letters, in the absence of difficulties with spelling or grammar. Patients with apraxic agraphia can therefore type or use a word processor without difficulty.

Testing for Apraxia

The bedside or clinic evaluation of apraxia relies on a set of semistandardized commands that are designed to explore the patient's ability to carry out specific movements involving the hands or face. A distinction between intransitive commands (not requiring an object), such as 'wave good-bye' or 'hitchhike,' and transitive commands ('use a hammer' or 'use a screwdriver') is typically made. Among the best-known standardized compilations of apraxia commands is the one included as part of the Boston Diagnostic Aphasia Exam (Goodglass and Kaplan, 1983). For research purposes, more detailed testing may include not only evaluating the patient's ability to carry out actions in response to verbal commands, but also the ability to imitate meaningful or meaningless movements or hand/finger postures performed by the examiner, and the ability to select the correct action from among multiple choices as demonstrated by the examiner (De Renzi, 1989). The most common errors in patients with apraxia include those of sequencing or timing, or using a body part as the tool (e.g., using the hand as a comb in response to 'show me how to comb your hair' instead of pretending to hold a comb.)

Subtypes of Apraxia

Several subtypes of apraxia are now recognized. First described by Arnold Pick (1851–1924), 'conceptual' or 'ideational apraxia' refers to the inability to perform commands that require multiple steps, such as folding a piece of paper, inserting it into an envelope and sealing the envelope. Although patients with ideational apraxia may be able to perform the individual components of the task, they have difficulties with the correct sequencing of the individual subcomponents. Ideational apraxia in its pure form is rare, and it may be more frequently observed in patients with diffuse cognitive impairment, such as dementia, than in patients with focal deficits secondary to stroke. 'Ideomotor apraxia' refers to an impairment of the timing, sequencing, and organization of gestures. Patients with this type of apraxia have difficulties demonstrating simple motor gestures, such as 'wave goodbye' and 'salute,' and the use of common tools, such as a hammer or screwdriver. This type of apraxia is usually associated with lesions involving the dominant parietal lobe.

A unique subtype of apraxia may occur with lesions that involve the anterior portions of the corpus callosum. It was first described by Liepman and Mass in 1907 and since that time, several case histories have been reported (Faglioni and Basso, 1985). Tumors, strokes, or traumatic lesions that interrupt the anterior portion of the corpus callosum can produce an apraxia that is limited to the left side of the body. No systematic case series have been published, and it is therefore not possible to determine how often such callosal lesions do not result in an apraxia (De Renzi, 1989). The presumed mechanism of callosal apraxia is that the lesion of the corpus callosum interrupts connections between language comprehension areas in the left hemisphere and motor areas controlling the left hand in the right hemisphere. In support of the verbal–motor disconnection hypothesis, a patient reported by Geschwind and Kaplan was unable to perform actions to verbal command, but was able to imitate gestures with his left hand (Geschwind and Kaplan, 1962). Other patients with callosal apraxia have not shown this dissociation between verbal and visual commands, however, but instead have shown left-hand apraxia regardless of stimulus modality. The hypothesis that a lesion of the corpus callosum by itself is sufficient to produce the syndrome of callosal apraxia has also been questioned in light of reports that patients with complete surgical lesions of this interhemispheric commissure (callosomectomy) typically do not show left-hand apraxia.

Patients with oral (sometimes also referred to as buccofacial) apraxia have difficulty performing movements involving the face, such as blowing out a match, sticking out their tongue, or whistling. Oral apraxia often coexists with Broca's aphasia, but it may also occur in the absence of aphasia. It is associated with lesions affecting the frontal operculum of the left hemisphere in right-handers.

Prevalence

Although apraxia is among the most common neuropsychiatric complications of stroke or other lesions involving the posterior left hemisphere in right-handers, the presence of the deficit is frequently overlooked for two reasons: first, the patient rarely complains of such symptoms, and second, because apraxia is most often associated with left hemisphere lesions, the symptoms may be masked or overshadowed by the co-occurring aphasia. The prevalence of apraxia among patients with a first left hemisphere stroke was reported to be 28% in one study (Donkervoort *et al.*, 2000). Other studies that have included patients with both left and right hemisphere stroke have reported a prevalence rate of only 7% (Pedersen *et al.*, 2001). This is consistent with the Liepman's original observation that apraxia occurs more frequently after left hemisphere stroke in right-handers.

Apraxia is also a common finding in some neurodegenerative disorders, including corticobasal degeneration and dementia with diffuse Lewy bodies. It

occurs less frequently in conditions such as closed head injury or demyelinating disorders of the central nervous system.

Cerebral Dominance for Motor Learning

Apraxia was initially thought to be secondary to a disconnection of verbal and motor areas of the brain. According to this hypothesis, verbal input could be processed in the traditional speech comprehension areas of the superior temporal lobe, but apraxia would result if a lesion prevented this information from reaching appropriate motor areas for execution. Consistent with this interpretation was the observation that performance to visual demonstration was often intact, and performance with real objects was also typically better preserved. It soon became clear, however, that the majority of cases of apraxia could not be explained by disconnection alone. To account for such cases, Liepman developed the concept of cerebral dominance for motor learning and control. According to his theory, as one hemisphere becomes dominant for language functions, one of the two hemispheres similarly develops into the dominant one for motor functions. On the basis of studies of both right- and left-handed patients with apraxia, Liepman also noted a strong relationship between hemispheric dominance for motor programming and handedness. The vast majority of right-handers develop apraxia after lesions of the contralateral (left) hemisphere, while left-handers most often develop apraxia after right hemisphere lesions.

Dissociation of Language and Praxis

Because of the overlapping representations of language and praxis in the posterior regions of the left hemisphere, the vast majority of right-handers develop both apraxia and aphasia after left hemisphere lesions. In some patients, however, the representation of language functions and praxis are in separate hemispheres. Although rare, such cases have been very important for our understanding of the complex interrelationships of praxis, handedness, and hemispheric dominance for motor and language functions.

One such patient was described by Heilman and his colleagues. The patient was a left-handed man who had suffered a large cerebral infarction in the anterior right hemisphere. The infarction involved brain regions that would have resulted in severe Broca's aphasia if the lesion had been in the left hemisphere. The patient did develop a left hemiparesis, but no aphasia, suggesting that the intact left hemisphere was in fact the language-dominant hemisphere. He did, however, develop a significant apraxia involving his (nonparalyzed) right arm. This could be explained if one hypothesized that the repository of skilled movements was in the right hemisphere, contralateral to his dominant **left** hand (Heilman *et al.*, 1973).

An opposite dissociation, apraxia but no aphasia after a large left hemisphere stroke in right-handers, is quite rare, but has been described in at least two cases. In one of these, the patient was a right-hander who suffered a massive left hemisphere stroke that involved most of the perisylvian language areas (Selnes *et al.*, 1982). Surprisingly, this produced only a transient aphasia but a long-lasting apraxia. These findings were interpreted as a rare case of mixed or right hemisphere language dominance in a right-hander, but with motor skill dominance in the left hemisphere, contralateral to the dominant hand. A second patient with a similar dissociation between praxis and language was reported by Selnes and colleagues (Selnes *et al.*, 1991). The patient was an 81-year-old right-handed male who suffered a massive left cerebral artery stroke. The radiological studies showed virtually complete destruction of the left hemisphere perisylvian language areas. Instead of the global aphasia that normally would have been associated with such a left hemisphere lesion in a right-hander, the patient developed a dense apraxia.

These cases of atypical language dominance in both right- and left-handers help demonstrate that aphasia and apraxia are dissociable, and provide support for the hypothesis that handedness is much more closely related to hemispheric laterality of motor control than to hemispheric laterality of language.

Anatomical Correlates

Although limb apraxia most often results from large lesions involving the dominant superior parietal lobe region, recent evidence suggests that apraxia may result from a spectrum of lesions affecting different nodes in a widely distributed network of higher-order motor functions. While frontoparietal regions may be the most crucial anchor points in this network, other nodes such as the supplementary motor area are now also recognized as being relevant for the neurological substrate of praxis.

Arabic

S Procházka, University of Vienna, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Arabic is the official language of 21 countries in the Middle East and North Africa, from Oman in the east to Mauritania in the west. This includes Israel, where Arabic is, after Hebrew, the second official language. Significant Arab minorities exist in Iran, Turkey, Chad, and Nigeria, as well as in western Europe and the Americas. With approximately 280 million native speakers, Arabic is by far the largest living representative of the Semitic language family. Because it is the language of the Koran and thus the liturgical language of Islam, Arabic also plays an important role for more than 1 billion Muslims worldwide.

History of the Language

Arabic is an offshoot of the Semitic branch of the Afro-Asiatic languages. According to the traditional classification of Semitic, Arabic is part of its southern subdivision and grouped with Ethiopic and South Arabian (by stressing the common $p > f$ shift and the internal plurals). In the 1970s, Hetzron proposed placing Arabic with Aramaic and Canaanite in a 'Central Semitic' group (stressing the imperfect pattern and the *t* as a marker for the first- and second-person singular perfect). The problem of the affiliation of Arabic within the Semitic languages continues to be discussed (see Faber, 1997).

Although people labeled Arabs are attested as early as the 9th century B.C.E. in Assyrian sources, the history and development of their language before the emergence of Islam, 1.5 millennia later, is largely unkown. Doubtless Arabic originated in the central and northern parts of the Arabian peninsula, later spreading northward to the edges of the Fertile Crescent. The first evidence of a language akin to Arabic are the so-called Ancient North Arabian inscriptions (5th century B.C.E. to approx. 4th century C.E.): these consist of thousands of short, and therefore linguistically scarcely informative, graffiti in a script derived from the South Arabian writing system and found mainly in western Arabia and southern Syria. There are traces of Arabic in the Aramaic inscriptions of the Nabateans and Palmyrenes – both certainly Arab people. Textual evidence of pre-Islamic Arabic is also found in a handful of inscriptions in early Arabic script from the 2nd to 6th centuries C.E.

Our richest source of pre-Islamic Arabic is a large corpus of orally transmitted poetry from the 6th and 7th centuries C.E., later compiled by Arab philologists. The language of these poems and, although not exactly identical to theirs, that of the Koran (proclaimed by Muhammad between circa 610 and 632) is usually termed 'Old Arabic.' These texts, although a kind of poetic koinè, contain phonetical, morphological, and lexical inconsistencies that reflect the actual dialectal differences between the spoken tribal vernaculars of the era (on these, see Rabin, 1951).

Arabic is the official language of 21 countries in the Middle East and North Africa, from Oman in the east to Mauritania in the west. This includes Israel, where Arabic is, after Hebrew, the second official language. Significant Arab minorities exist in Iran, Turkey, Chad, and Nigeria, as well as in western Europe and the Americas. With approximately 280 million native speakers, Arabic is by far the largest living representative of the Semitic language family. Because it is the language of the Koran and thus the liturgical language of Islam, Arabic also plays an important role for more than 1 billion Muslims worldwide.

History of the Language

Arabic is an offshoot of the Semitic branch of the Afro-Asiatic languages. According to the traditional classification of Semitic, Arabic is part of its southern subdivision and grouped with Ethiopic and South Arabian (by stressing the common $p > f$ shift and the internal plurals). In the 1970s, Hetzron proposed placing Arabic with Aramaic and Canaanite in a 'Central Semitic' group (stressing the imperfect pattern and the *t* as a marker for the first- and second-person singular perfect). The problem of the affiliation of Arabic within the Semitic languages continues to be discussed (see Faber, 1997).

Although people labeled Arabs are attested as early as the 9th century B.C.E. in Assyrian sources, the history and development of their language before the emergence of Islam, 1.5 millennia later, is largely unkown. Doubtless Arabic originated in the central and northern parts of the Arabian peninsula, later spreading northward to the edges of the Fertile Crescent. The first evidence of a language akin to Arabic are the so-called Ancient North Arabian inscriptions (5th century B.C.E. to approx. 4th century C.E.): these consist of thousands of short, and therefore linguistically scarcely informative, graffiti in a script derived from the South Arabian writing system and found mainly in western Arabia and southern Syria. There are traces of Arabic in the Aramaic inscriptions of the Nabateans and Palmyrenes – both certainly Arab people. Textual evidence of pre-Islamic Arabic is also found in a handful of inscriptions in early Arabic script from the 2nd to 6th centuries C.E.

Our richest source of pre-Islamic Arabic is a large corpus of orally transmitted poetry from the 6th and 7th centuries C.E., later compiled by Arab philologists. The language of these poems and, although not exactly identical to theirs, that of the Koran (proclaimed by Muhammad between circa 610 and 632) is usually termed 'Old Arabic.' These texts, although a kind of poetic koinè, contain phonetical, morphological, and lexical inconsistencies that reflect the actual dialectal differences between the spoken tribal vernaculars of the era (on these, see Rabin, 1951).

The expansion of Arab territory during the Islamic conquests (7th–8th centuries) made Arabic the language of communication, administration, and liturgy for an empire that stretched from central Asia to the Atlantic. The form of Arabic described, systematized, and canonized by the Arab grammarians and lexicographers between the 8th and 10th centuries is called Classical Arabic (CA). It remains the only universally accepted standard of the language. During the Golden Age of the Abbasid caliphate (9th–10th centuries) CA became the linguistic vehicle of a highly developed civilization that brought forth a rich literature, including *belles-lettres* and religious and scientific works. The hegemony of Arabic during the Middle Ages, and its prestige as the 'sacred' language in which the holy book of the Koran had been revealed to humankind, have influenced the languages of all Muslim people, written and unwritten. Thus, the lexicon of languages such as Persian (Western Farsi), Urdu, Turkish, or Swahili include numerous CA words. In many Muslim countries, Arabic has continued to be the language of religious treatises, and the teaching of it forms part of school curricula.

The Present Situation

Modern Standard Arabic

During Ottoman rule over most parts of the Arab world (from the 16th century onward), Arabic stagnated linguistically and literarily. Thus, in the early 19th century, when Arab intellectuals began to 'discover the West' and to translate European works into Arabic, they soon recognized its lexical shortcomings. This was the starting point of Modern Standard Arabic (MSA). MSA is practically identical in phonology, morphology, and syntax to CA, but it exhibits major differences from it in lexicon, phraseology, and style. After World War I, the modernization of Arabic continued in the language academies of Damascus, Cairo, and other capitals, which coined and still are coining thousands of neologisms. But not all the problems have been solved and, particularly in technical and scientific terminology, Arabic has not yet reached the standard of European languages. Competition among the academies frequently resulted in several terms for one and the same thing, and many academic neologisms have not been accepted by the speech community, which often prefers a loanword from English or French. In the standard language, loans play a remarkably minor role, but the phraseology and style of MSA is deeply influenced by English (and in the Maghreb by French), above all in the language of the media. Thus, it is justified to call MSA a register of Arabic clearly differentiated from the classical language. The importance of MSA is that, as the only accepted medium of written and formal oral communication, it constitutes the tie that linguistically binds the Arab world together. However, MSA has to be learned in school because the native tongue of every Arabic speaker remains his or her local dialect as used in everyday life by all social strata. Therefore, MSA is almost completely limited to written use and to highly formal speech (news, official speeches, and academic discourse). Actually, this diglossic situation has been inherent in Arabic for at least the past millennium. The two linguistic layers are, of course, in a state of permanent mutual influence, and between the extremes of 'pure standard' and 'plain colloquial' Arabic are levels such as 'educated colloquial.' During the past decades, active and, especially, passive knowledge of MSA has significantly increased because of better education and the media. This trend was recently reinforced by the establishment of pan-Arabic satellite channels, which enjoy great popularity. Thus, even if MSA remains restricted to the domain of written and formal speech, a continually growing portion of the speech community will be able to participate in it.

Arabic Dialects

The various dialects belong to a language type called 'New Arabic,' whereas both CA and (in spite of its label 'modern') present-day MSA are 'Old Arabic.' The term 'Middle Arabic' does not denote, as we might assume, an intermediate chronological stage but a form of written Arabic exhibiting deviations from the standard norm due to the influence of 'New Arabic', (i.e., the dialects; see Veerstegh, 1997: 114–129).

Although there are numerous typological differences, it is widely accepted, especially among Arabic speakers themselves, that the distinction between Old and New Arabic is the presence or absence of the case and mood endings (in Arabic, *'i'rāb*). The question of when and how the transformation from the old to the new type of Arabic happened is one of the most intriguing and discussed issues of Arabic studies (good summaries are Holes, 1995: 7–14; Versteegh, 1997: 93–113). There are indications from inscriptions that in the speech of the Nabateans the case system may have broken down as early as the 1st century C.E. If this is true, the new type of Arabic would have been spread along the trade routes of northern and western Arabia before the rise of Islam. Nevertheless, it seems very likely that in the time of Muhammad the structure of everyday Arabic was not identical, but quite close, to the language of the poetry and the Koran. Only the social and political turmoils during and after the conquests resulted in a rapid shift

to New Arabic. It should be emphasized, however, that Arabic developed along a line of internal linguistic trends common to all modern Semitic languages and clearly traceable before that time. The argument, often urged by the Arabs themselves, that these changes were mainly caused by so many non-Arabs using Arabic must be rejected.

The new type of Arabic spread among the urban centers of the Fertile Crescent and Egypt (the countryside had not yet been Arabicized) in the aftermath of the conquests. The language of the Bedouins, however, was not, or was only slightly, affected by these changes until approximately 2 centuries later. Ferguson (1959) explained the relative homogeneity of the urban dialects by the existence of a single koinè in the 7th–8th centuries. Although this theory is not tenable in its entirety, it was the starting point of a fruitful scientific discussion. From the present point of view, it seems very likely that the resemblances among the urban dialects are the consequence of continous convergence and the mutual leveling of several regional koinai (see the summary in Miller, 1986).

The greatest typological differences are found between the sedentary (urban and rural) dialects and the Bedouin dialects. Thus, the speech of a sedentary Bedouin living in the outskirts of Tunis, for example, typically is closer to that of a Bedouin of Mauritania living 2000 miles away than it is to the speech of his neighbors speaking the dialect of the city of Tunis. Another sharp division separates the North African or Maghrebi dialects (including Maltese) west of Egypt from those to the east. The eastern dialects themselves can be divided into four large groups: (1) Arabian Peninsula, (2) Mesopotamia, (3) Syria and Palestine, and (4) Egypt, Sudan, and Chad (see Fischer and Jastrow, 1980). Audio files of a great number of dialects are available on the Semitic Sound Archive website of the University of Heidelberg.

Structure of Arabic

Phonology

The Arabic vowel system consists of three vowels /a, i, u/, with a phonemic contrast of short and long, for example, [mudiːrunaː] 'our director' versus [mudiːruːnaː] 'our directors'. In contrast to this relatively small number of vowels, Arabic possesses 28 consonant phonemes (see Table 1), also with a phonemic short-long contrast, for example, [ħamaːm] 'pigeons' versus [ħamːaːm] 'bath' (as is usual, isolated Arabic nouns are cited without their case endings). The characteristic sound of Arabic is created mainly by a couple of consonants articulated in the velar and postvelar regions of the vocal tract and by the four velarized (also called 'emphatic') consonants that also have a lowering effect on adjacent vowels.

The realization of the consonant phonemes in MSA reflects almost completely the situation of Old Arabic. Exceptions are *j* [dʒ] (ج), which was most probably pronounced [ɟ], and the somewhat problematic sound *ḍ* [ɗ] (ض). There is an ongoing discussion on the original pronunciation of this consonant, which was so characteristic that Arabic was even called 'the language of the letter *ḍād*' (*lughat aḍ-ḍād*). Most likely it was either a velarized lateral fricative [ɬ] or a lateralized variety of *ḍ* [ɗˡ] (the latter perhaps reflected in such Spanish loans from Arabic as *alcalde* < *'al-qāḍī* 'the judge').

The present-day standard pronunciation of the consonants shows no regional variations other than the sound ẓ [ð̞] (ظ), which in many countries (e.g., Syria and Egypt) is pronounced ẓ [ɮ].

Except in religious utterances (i.e., the recitation of the Koran), other alterations are widely accepted, which make it quite easy to recognize the country of a given news broadcast. The most striking among these is the replacement of [dʒ] by [g] in Egypt or by [ʒ] in the Levant and large parts of North Africa.

The syllabic structure of CA is restricted to three types: CV, CVː, and CVC (under certain conditions also CaːC/CayC). However, in MSA final short vowels are often omitted, so CVːC and CVCC are also found. An Arabic word cannot begin with a vowel, and two vowels must be separated by no fewer than one consonant but by no more than two consonants.

Phonology of the Dialects Leaving aside the lexicon, the greatest difference among Arabic dialects is in

Table 1 The consonants of standard Arabic

	Bilabial	*Labiodental*	*Dental|Alveolar|Postalveolar*	*Palatal*	*Velar*	*Uvular*	*Pharyngeal*	*Glottal*
Plosive	b		ʈ d ɗ		k	q		ʔ
Nasal	m		n					
Trill			r					
Fricative		f	θ ð ð̞ | s ɮ z (ɮ)[a] | ʃ dʒ		x ɣ		ħ ʕ	h
Approximant		ʋ		j				
Lateral approximant			l					

[a]The sound /ɮ/ is used in some countries (e.g., Egypt, Syria, and Lebanon) instead of ð̞.

phonology. The following summary provides only a general overview. In all modern dialects (with negligible exceptions in Yemen) the non-initial [ʔ] is lost and the two sounds ð̣ (ظ) and ḍ (ض) are mingled into one sound [ð̣]. The consonants that most frequently exhibit changes compared to CA are (1) the three interdental fricatives [ð], [θ], and [ð̣] that, in the majority of the sedentary dialects, have been shifted to corresponding postdental stops (i.e., [d], [t], [ḍ]); (2) the affricate [dʒ], which is pronounced [ɟ] in Central Arabia and the Sudan, [ʒ] in large parts of North Africa and the Levant, [g] in Lower Egypt, and [j] along the Arab Gulf; and (3) the reflexes of CA *q* (usually indicates whether a dialect is of the Bedouin or the sedentary type), which in Bedouin dialects has a voiced pronunciation ([g], [dz], [dʒ]) but in sedentary dialects is usually unvoiced ([q] or, as a typical urban phenomenon, [ʔ]).

Excluding the few that have been lengthened, all final short vowels of CA have been lost. There is also an almost universal tendency toward eliding unstressed short vowels (especially [i] and [u]) in open syllables (e.g., Cairo (Egyptian Spoken Arabic): ['ʃirib] 'he drank' versus ['ʃirbu] 'they drank'). Many sedentary dialects exhibit a reduction of the inventory of short vowels from three to two (either a/ə or u/ə), whereas the majority of both Bedouin and sedentary dialects have developed a system of five long vowels [aː, eː, iː, oː, uː] as a result of the monophthongization of [ai] > [eː] and [au] > [oː].

Morphology

Derivational Morphology In all layers of Arabic, the bulk of the vocabulary is built on the principle of root and pattern. To express certain semantic terms (i.e., words), a purely consonantal root carrying the basic semantic information is combined with a limited set of patterns using a fixed sequence of consonants, vowels, and optional prefixes and suffixes. Most of the roots consist of three consonants called radicals. Those with four consonants are by no means rare, but are often merely extensions of triconsonantal roots. A few words of the most elementary vocabulary have only two radicals, for example, *'ab* 'father', *yad* 'hand', and *mā'* 'water'. Such words, and the numerous instances of triconsonantal roots with two common radicals expressing similar semantic concepts, have fueled speculations that the original system was built on a biconsonantal root system.

Many patterns are semantically and morphologically ambiguous; that is, one and the same pattern can serve for different semantic concepts and can be used for both verbs and nouns and for both singular and plural. Nevertheless, there are also patterns that are used exclusively for verbs or for certain semantic or morphological classes.

- CuCayC is the pattern of diminutives, for example, *kuwayt* 'small fortress'.
- maCCaC/-a is used for nouns of place, for example, *maktab* 'office', *maktaba* 'library' (root *k-t-b* 'writing').
- miCCaC/miCCāC is used for instruments, for example, *miṣ'ad* 'elevator' (root *ṣ-'-d* 'ascending'), *miftāḥ* 'key' (root *f-t-ḥ* 'opening').
- CaCCāC denotes professions, for example, *jazzār* 'butcher' (root *j-z-r* 'slaughtering').
- CaCCāCa is used for professions of females and instruments, for example, *ghassāla* 'washerwoman, washing machine' (root *gh-s-l* 'washing'), *barrāda* 'refrigerator' (root *b-r-d* 'cold').

As can be seen from *miṣ'ad* and *barrāda,* the system of derivation is widely used for the creation of neologisms. Although noun patterns are quite numerous (approximately 90 in CA) and are mostly not clearly related to semantic classes, the derivation of verbs is practically limited to 10 stems for triconsonantal roots and two for quadriconsonantal roots. Each stem has a set of five patterns reserved for the perfect and imperfect base, for the active and passive participle, and for a verbal noun (also called infinitive, lexicalized, i.e., not predictable, in stem I). As is shown in Table 2, certain functions can generally be attributed to each verb stem, although in detail the situation is highly complex (see the overview in Cuvalay-Haak, 1997: 95–108).

The principle is exemplified by the root *q-ṭ-'* 'cutting'.

- I: *qaṭa'-a* 'to cut (in two)'.
- II: *qaṭṭa'-a* 'to cut into pieces'.
- III: *qāṭa'-a* 'to dissociate'.
- IV: *'aqṭa'-a* 'to make cut'.
- V: *taqaṭṭa'-a* 'to be cut off'.
- VI: *taqāṭa'-a* 'to break off mutual relations'.
- VII: *'inqaṭa'-a* 'to be cut off'.
- VIII: *'iqtaṭa'-a* 'to take a part'.

Note that no root is combined with all 10 stems.

The root-pattern system of derivation is responsible for the remarkable uniformity of the Arabic lexicon. Only a very few types of roots, above all those containing the two weak consonants *w* and *y*, cause changes in most patterns; but, because even these follow certain rules, Arabic morphology is almost completely free of irregularities.

Noun Inflection The class of nouns comprises substantives, adjectives, and numerals; the categories gender, number, definiteness/indefiniteness, and case are

Table 2 Stems of triconsonantal verbs in Standard Arabic

Stem	*Perfect*	*Imperfect*	*Verbal noun*	*Active participle*[a]	*General functions*	*Frequency/MSA*[b]
I	CaCVC-	ya-CCVC-	CVCC/CVCVC[c]	CāCiC-	basic	40.07%
II	CaCCaC-	yu-CaCCiC-	taCCīC-	muCaCCiC-	causative/intensive	14.28%
III	CāCaC-	yu-CāCiC-	muCāCaC-at-[d]	muCāC:C	conative and others	5.14%
IV	'aCCaC-	yu-CCiC-	'iCCāC:C	muCCiC-	causative/factitive	10.56%
V	taCaCCaC-	ya-taCaCCaC-	taCaCCuC-	mutaCaCCiC-	reflexive/passive	10.80%
VI	taCāCaC-	ya-taCāCaC-	taCāCuC-	mutaCāCiC-	reciprocal	4.44%
VII	'inCaCaC-	ya-nCaCiC-	'inCiCāC-	munCaCiC-	intransitive/passive	2.93%
VIII	'iCtaCaC-	ya-CtaCiC-	'iCtiCāC-	muCtaCiC-	reflexive	6.94%
IX	'iCCaCC-	ya-CCaCC-	'iCCiCāC-	muCCaCC-	colors[e]	0.19%
X	'istaCCaC-	ya-staCCiC-	'istiCCāC-	mustaCCiC-	reflexive and others	4.67%

[a]The passive participle has an *a* instead of *i* in the last syllable, except in stem I, where the pattern maCCūC-is used.
[b]Relative frequency of the stems in a modern dictionary; from Cuvalay-Haak (1997: 88).
[c]Both occur also with the suffix-*at*; there are numerous other patterns, in CA approximately 40.
[d]And CiCāC-.
[e]For instance *'iḥmarr-a* 'to be red, to blush'.

differentiated. Arabic has two genders, masculine and feminine, the latter marked usually by the suffix-*a(t)* and in some noun patterns by *-ā'/-ā*. Among the unmarked feminines are nouns denoting beings of the female sex (e.g., *'umm* 'mother'), paired parts of the body (e.g., *'ayn* 'eye'), and some basic concepts of nature (e.g., *'arḍ* 'earth', *shams* 'sun', and *nār* 'fire').

The number system is trifold: singular (unmarked), dual (suffix *-āni*), and plural. The plural is formed either by suffixation (MASC PL *-ūna*; FEM PL *-āt*) or more frequently by a complete restructuring of the word (thus the term internal or 'broken' plural), for example, *bayt* 'house', *buyūt* 'houses'; *kitāb* 'book', *kutub* 'books'; *miftāḥ* 'key', *mafātīḥ* 'keys'. A number of patterns (especially those containing three vowels) are restricted to plurals, but many others are used for both numbers; the pattern CiCāC, for instance, is singular in *kitāb* 'book', but plural in *jibāl* 'mountains' (for broken plurals see, Murtonen, 1964). Indefiniteness is usually expressed by a final *-n*, for example, *bayt-u-n* 'a house'; definiteness is usually expressed by the proclitic article *'al-* (assimilated to dentals, sibilants, *n*, and *r*), by a pronominal suffix, or by a following genitive, for example, *'al-bayt-u* 'the house', *bayt-u-nā* 'our house', *bayt-u ḥasan-i-n* 'Hasan's house'.

Arabic has the three cases, nominative, genitive, and accusative, which are differentiated in the singular and in broken plurals by declensions marked by the final vowel, for example, NOM *'al-bint-u*, GEN *'al-bint-i*, ACC *'al-bint-a* 'the girl'. The dual and external plural have common forms for the genitive and accusative (DUAL *-ayni*, MASC PL *-īna*, FEM PL *-āt-i-n*), a feature that is shared by a second (called 'diptote') type of declension (NOM *-u*, GEN/ACC *-a*) used primarily in female or foreign personal names and in certain plural patterns (in indefinite status).

Pronouns In pronouns, and hence in verbal inflection, Arabic distinguishes between masculine and feminine in all but the first person and the dual (see Table 3). Independent personal pronouns exist only in the nominative; for the other cases, suffixed forms are used, for example, *'anti marīḍ-at-u-n* 'you (FEM SING) are ill', *bayt-u-ki* 'your (FEM SING) house', *qabbala-ki* 'he kissed you (FEM SING)'.

The relative pronouns and the two sets of demonstrative pronouns (for near and far deixis) also differentiate gender and number.

Verb Inflection Arabic has a twofold system for the inflection of finite verbs: a suffix-based conjugation, traditionally called 'perfect', and a prefix-based conjugation, called 'imperfect'. For both of these bases, a second set of vowel patterns exists to form a passive voice, for example, in stem I *ḍarab-a* 'he hit' versus *ḍurib-a* 'he was hit'; *ya-ḍrib-u* 'he hits' versus *yu-ḍrab-u* 'he is hit'. Usually the passive is used when the agent of a sentence is not mentioned or to express impersonality, for example, *ya-dkhul-u* 'he enters' versus *yu-dkhal-u* 'one enters'.

The imperfect has four moods, morphologically marked by different suffixes (the examples in parentheses are the forms of 'to write' in third-person singular masculine): indicative (*ya-ktub-u*), subjunctive (*ya-ktub-a*), jussive (*ya-ktub-Ø*), and the so-called energetic (*ya-ktub-anna*), which is used in CA to express very strong assertions but is almost obsolete in MSA. The imperative is basically a subset of the jussive without prefixes. The verb conjugation expresses person, gender, and number. The system is, except for an additional dual for third-person feminine, analogous to the pronouns given in Table 3.

Table 3 Personal pronouns

	Singular		*Dual*		*Plural*	
	Independent	*Suffixed*	*Independent*	*Suffixed*	*Independent*	Suffixed
1	ʼanā	-nī |-ī[a]			naḥnu	-nā
2 MASC	ʼanta	-ka	ʼantumā	-kumā	ʼantum	-kum
3 FEM	ʼanti	-ki	ʼantumā	-kumā	ʼantunna	-kunna
3 MASC	huwa	-hū/-hī	humā	-humā/-himā	hum	-hum/-him
3 FEM	hiya	-hā	humā	-humā/-himā	hunna	-hunna/-hinna

[a]*-nī* is used with verbs,*-ī* with nouns and prepositions.

Morphology of the Dialects Generally speaking, no radical structural changes appear in the morphology of the dialects as compared to CA. Morphological derivation by applying the principle of root and pattern has been slightly simplified (there are fewer patterns compared to CA), but has remained productive. The most striking morphological difference between CA/MSA and all dialects is the lack of a case system. The indefinite marker *-n* has not survived except in some Bedouin dialects where it is found in a few syntactical positions such as attribution (e.g., North Syrian Bedouin: *bēt-in chibīr* 'a big house'). Some dialects (e.g., Iraqi), however, have developed an indefinite article.

All dialects lack dual forms of the pronouns and verbs, and most sedentary dialects have given up gender distinctions in the plural and those in North Africa no longer have gender distinctions in the second-person singular, as well. Together with nouns, the category dual is fully productive in the east, but in the sedentary dialects west of Egypt the dual is usually expressed by the numeral 'two' followed by a noun in the plural.

For the verbs, the perfect conjugation has not changed significantly. In the imperfect, however, the category mood is not expressed by internal inflection (a result of the loss of final short vowels) but, instead, where not completely obsolete, by modifiers prefixed to the verb. For example, in Damascus *b-yəshrab* 'he drinks' roughly corresponds to the indicative and *yəshrab* to the subjunctive/jussive. The formation of an internal passive voice seems to be limited to a few Bedouin dialects. In other dialects, certain verbal stems (especially VII and VIII) are used to express passive voice, for example, Damascus: *ḥabas* 'he imprisoned' (stem I) versus *nḥabas* 'he was imprisoned' (stem VII).

Syntax

Tense and Aspect The verbal system of Arabic can be described as a combination of aspect and time reference. The suffix conjugation (called 'perfect') serves for the past and for the perfective (completed/factual) aspect, and the prefix conjugation serves for the nonpast (present/future) and for the imperfective (noncompleted/ongoing) aspect, including habituality, continuousness, and progressivity. An exception is the combination of the negation *lam* and the jussive mood, which indicates the negation of the perfect (e.g., *lam ya-ktub* 'he has not written').

The Arabic tense system is to a high degree a relative one. In main clauses, the temporal reference point is usually the moment of speaking, whereas in complement clauses the time has to be derived by reference from the main verb. Verbs in the perfect are also used in conditional clauses, in wishes and curses, and for assertions of factuality:

Allāh-u ʻazz-a wa-jall-a
God-NOM *was.mighty*-PERF *and-was.sublime*-PERF
'God, he is mighty and sublime'

Participles do not mark any particular time reference, but frequently serve for a resultant aspect; that is, they describe an action that bears relevance to the moment of speaking.

Word Order The basic neutral word order of Arabic is VSO, but thematization of the subject is achieved by SVO. The latter therefore is not possible if the subject is indefinite, in which case sometimes also VOS appears.

The foreground/background distinction also influences word order. Generally VS is used for foreground information and events, and SV for background information and descriptions.

An adjectival attribute follows its head noun and agrees with it in case, in definiteness, and – with restrictions – in gender and number:

bayt-u-n kabīr-u-n
house.MASC.SING-NOM-INDEF *big*.MASC.SING-NOM-INDEF
'a big house'

fī l-qalʻ-at-i l-kabīr-at-i
in the.DEF-*fortress*.SING-FEM-GEN *the*.DEF-*big*.SING-FEM-GEN
'in the big fortress'

Nominal annexations are in the genitive case and follow the head noun, which is morphologically determined (i.e., in the so-called *status constructus*). Indefinite/definite is therefore indicated solely by the noun annexed to it, for example, *bāb-u bayt-in* 'a door of a house' versus *bāb-u l-bayt-i* 'the door of the house'. Although the number of annexations is theoretically unrestricted, there can be only one head noun. In phrases such as 'the director and the teachers of the school' the second head noun follows the genitive and takes a suffix referring to it:

mudīr-u l-madras-at-i wa-mu'allim-ū-hā
director.MASC-NOM *the-school*-FEM-GEN *and-teachers*-NOM-PL-*her*.FEM
'the director and the teachers of the school'

Under the influence of European languages, this rule is frequently ignored in MSA.

Agreement Strict agreement in gender and number exists only in the singular. Nouns in the plural agree with feminine singular unless they denote human beings.

kutub-u-n qayyim-at-u-n
books.MASC.PL-NOM-INDEF *precious*-FEM.SING-NOM-INDEF
'precious books'

rijāl-u-n kirām-u-n
men.MASC.PL-NOM-INDEF *generous*.MASC.PL-NOM-INDEF
'generous men'

'ar-rijāl-u katab-ū
the-men.MASC.PL-NOM.DEF *wrote*-MASC.PL
'the men wrote'

'al-banāt-u ḍaḥik-na
the-girls.FEM.PL-NOM.DEF *laughed*-FEM.PL
'the girls laughed'

However, if the verb precedes its nominal subject, it agrees in gender but not in number:

katab-a r-rijāl-u
wrote-MASC.SING *the-men*.MASC.PL-NOM.DEF
'the men wrote'

ḍaḥik-at-i l-banāt-u
laughed-FEM.SING *the-girls*.FEM.PL-NOM.DEF
'the girls laughed'

A special case of agreement occurs with the cardinal numbers from 3 to 10, which take the opposite gender of the counted noun's singular, itself added in the genitive plural:

khams-u sanaw-āt-i-n [san-at-u-n]
five.MASC-NOM *years*-PL-GEN-INDEF [*year*-FEM.SING-NOM-INDEF]
'five years'

khams-at-u 'ayyām-i-n [yawm-u-n]
five-FEM-NOM *days*.PL-GEN-INDEF [*day*.MASC.SING-NOM-INDEF]
'five days'

Equational Sentences Positive equational sentences in the present have no copula:

'al-bayt-u kabīr-u-n
the-house.MASC.SING-NOM.DEF *big*.MASC.SING-NOM-INDEF
'the house is big'

'anti ṭabīb-at-u-n
you.FEM.SING.NOM *physician*-FEM.SING-NOM-INDEF
'you (FEM) are a physician'

For the negated present, the special verb *laysa* 'to be not' is used; in all other cases, appropriate forms of the verb *kān-a* 'to be' appear. Both verbs exhibit the pecularity that their nominal complement is in the accusative:

'al-bayt-u laysa/kāna kabīr-a-n
the-house-NOM *is-not/was* *big*-ACC-INDEF
'the house is not/was big'

Subordination Temporal, final, causative, and other clauses are usually introduced by subordinating conjunctions such as *lammā* 'when', *li-* 'in order to', and *li-'anna* 'because'.

Constructions with the conjunction *wa-* 'and' are frequently used to express simultaneousness of actions or events (in Arabic, called *ḥāl*, 'circumstance' sentence):

dakhal-a l-ghurfata
entered.PAST-3.SING *the-room*
wa-huwa yaḍḥak-u
and-he *laughs*.PRES-INDIC
'he entered the room laughing'

Relative Clauses In Arabic, relative clauses are complete sentences that are normally linked to their head by a personal pronoun referring to it. A relative pronoun, which agrees in number and gender, is used only if the head is definite:

'al-bint-u llatī hiya faqīr-at-un
the-girl-NOM REL.PRON.SING.FEM *she* *poor*
'the girl who is poor'

'al-bint-u llatī ra'ay-tu-hā 'amsi
the-girl-NOM REL.PRON.SING.FEM *saw-1*.SING-*her*.ACC *yesterday*
'the girl whom I saw yesterday'

’al-bint-u	llatī	māt-at
the-girl-NOM	REL.PRON.SING.FEM	*died-3*.FEM
’umm-u-hā		
mother-NOM-*her*.GEN		

‘the girl whose mother has died’

bint-u-n	māt-at	’umm-u-hā
girl-NOM-INDEF	*died-3*.FEM	*mother*-NOM-*her*.GEN

‘a girl whose mother has died’

Syntax of the Dialects In principle, most dialects have preserved the combined time aspect system, although there are tendencies toward a stricter tense system (perfect for past, imperfect for nonpast). Frequently found as a discourse mechanism, however, is the narrative imperfect, in which a single past-time reference gives the frame for a following series of imperfective verb forms describing past actions or events. The perfect aspect expressed by the participle has become a well-established category in many, particularly eastern, dialects.

A great variety of auxiliary verbs (also called aspectualizers) exists for emphasizing punctual, durative, ingressive, progressive, and other aspects (see, for Cairo, Eisele, 1999).

Regarding word order, recent studies (Dahlgren, 1998; Brustad, 2000) have shown that the alleged preference of the dialects for SV order is true only for some urban dialects. On the whole, the same principles of thematization and foreground/background distinction obtain in the spoken vernaculars: “VSO represents the dominant typology in event narration, while SVO functions as topic-prominent typology that is used to describe and converse” (Brustad, 2000: 361). Particularly in dialogs, OVS is very frequent in topic-prominent structures, in which case a pronominal suffix has to mark the original place of the object, for example, in the Cairene dialect:

ukht-ak	shuf-t-aha	mbāriḥ
sister-your	*saw-1*.SING-*her*	*yesterday*

‘I saw your sister yesterday’

Agreement of nonhuman plural with feminine singular is possible, but in nearly all dialects ‘logical’ agreement is widely found. In the dialect of Damascus, both of the following phrases are equally acceptable: *byūt ẓghīre* ~ *byūt ẓghār* ‘small houses’. Which of the two is used depends on semantic, idiomatic, and stylistic features insufficiently investigated in detail. In general, the word order has no influence on agreement; that is, a verb usually agrees with its nominal subject in number whether the noun precedes or follows the verb.

Many dialects have developed so-called ‘genitive exponents,’ particles that are used under certain conditions for an analytic linking of two nouns or a noun and a pronoun suffix instead of a direct annexation. For example, in Arab Gulf dialect:

mēz	māl	ṭa‘ām
table	GEN PRT	*meal*

‘dining table’

and in Cairo dialect:

il-baṣbōr	bitā‘-i
the-passport	GEN PRT-*my*

‘my passport’

Etymologically most of these particles can be traced back to a word meaning ‘property’ or ‘right’. The choice whether an analytic or a synthetic construction is preferred depends on stylistic, semantic, and syntactical principles (Eksell Harning, 1980).

Arabic as an Introflecting Language

J C E Watson, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

In some languages, words are constructed or partially constructed not through the concatenation of linearly separable morphemes (e.g., English un-accept-able), but by the interdigitation of morphological forms which individually do not constitute self-standing phonological wholes. This type of morphology is variably termed in the literature introflectional, nonconcatenative (McCarthy, 1981), or transfixing (Bauer, 2003). It is a pervasive feature of the Semitic languages, and is particularly highly developed in Arabic. A simple example of introflection in Arabic is provided by *katab* 'wrote,' consisting of the root *k-t-b* {write}, the template CVCVC {PERF} and the vocalic melody a-a {ACT}.

Although introflection is a central feature of Arabic, most inflectional and some derivational categories are expressed through affixation; many derivational categories, which are expressed principally by introflection, take complementary prefixes or, less commonly, suffixes. This entry focuses on the morphology of Modern Standard Arabic, the formal written-based variety of the language, although many of the features outlined here are also found in the hundreds of Arabic dialects identifiable across the Arab world. The entry deals first with introflecting morphology in Arabic, sometimes in combination with affixation, and goes on to consider how introflection interacts with inflecting morphology.

Root and Pattern

Basic noun and verb stems in Arabic comprise a consonantal root and a pattern. The pattern can be further divided into two elements – a prosodic template and a vocalic melody. Most consonantal roots are triliteral. The root prototypically expresses the content meaning of the word, the pattern functional meaning. The association of the consonantal root and vocalic melody with the prosodic template is illustrated for the verb stem *katab* 'wrote.ACT' in **Figure 1**.

The consonantal root is always fully independent of the prosodic template; the vocalic melody, by contrast, shows independence for relatively few morphological categories; such examples include *katab* 'wrote.ACT' versus *kutib* 'wrote.PASS' in which the vocalic melody alone expresses voice. However, in the word *ʕilaaj* 'healing; treatment,' which comprises the consonantal root *ʕ-l-j* {heal; treat}, the prosodic template CVCVVC, and the vocalic melody *i-a*, the combination of the latter two expresses the category of verbal noun, rather than either the prosodic template or the vocalic melody independently.

Verbal Morphology

As illustrated in **Table 1**, Modern Standard Arabic has one basic verb form (form I) and nine derived

In some languages, words are constructed or partially constructed not through the concatenation of linearly separable morphemes (e.g., English un-accept-able), but by the interdigitation of morphological forms which individually do not constitute self-standing phonological wholes. This type of morphology is variably termed in the literature introflectional, nonconcatenative (McCarthy, 1981), or transfixing (Bauer, 2003). It is a pervasive feature of the Semitic languages, and is particularly highly developed in Arabic. A simple example of introflection in Arabic is provided by *katab* 'wrote,' consisting of the root *k-t-b* {write}, the template CVCVC {PERF} and the vocalic melody a-a {ACT}.

Although introflection is a central feature of Arabic, most inflectional and some derivational categories are expressed through affixation; many derivational categories, which are expressed principally by introflection, take complementary prefixes or, less commonly, suffixes. This entry focuses on the morphology of Modern Standard Arabic, the formal written-based variety of the language, although many of the features outlined here are also found in the hundreds of Arabic dialects identifiable across the Arab world. The entry deals first with introflecting morphology in Arabic, sometimes in combination with affixation, and goes on to consider how introflection interacts with inflecting morphology.

Root and Pattern

Basic noun and verb stems in Arabic comprise a consonantal root and a pattern. The pattern can be further divided into two elements – a prosodic template and a vocalic melody. Most consonantal roots are triliteral. The root prototypically expresses the content meaning of the word, the pattern functional meaning. The association of the consonantal root and vocalic melody with the prosodic template is illustrated for the verb stem *katab* 'wrote.ACT' in Figure 1.

The consonantal root is always fully independent of the prosodic template; the vocalic melody, by contrast, shows independence for relatively few morphological categories; such examples include *katab* 'wrote.ACT' versus *kutib* 'wrote.PASS' in which the vocalic melody alone expresses voice. However, in the word *ʕilaaj* 'healing; treatment,' which comprises the consonantal root *ʕ-l-j* {heal; treat}, the prosodic template CVCVVC, and the vocalic melody *i-a*, the combination of the latter two expresses the category of verbal noun, rather than either the prosodic template or the vocalic melody independently.

Verbal Morphology

As illustrated in Table 1, Modern Standard Arabic has one basic verb form (form I) and nine derived

Figure 1 Association of consonantal root and vocalic melody.

Table 1 Verb forms I–X

Typical meaning extension	*Form*	*PERF ACT*	*Gloss*	*PERF PASS*	*IMPERF ACT*	*IMPERF PASS*
	I	katab	write	kutib	yaktub	yuktab
causative	II	kattab	make s.o. write	kuttib	yukattib	yukattab
attempt	III	kaatab	correspond with s.o.	kuutib	yukaatib	yukaatab
causative	IV	ʔaktab	dictate	ʔuktib	yuktib	yuktab
reflexive of II	V	takattab	NA	tukuttib	yatakattab	yutakattab
reflexive of III	VI	takaatab	write to e.o.	tukuutib	yatakaatab	yutakaatab
medio-passive	VII	inkatab	subscribe	unkutib	yankatib	yunkatab
reflexive	VIII	iktatab	be recorded	uktutib	yaktatib	yuktatab
be/come a color/defect (e.g., red/lame)	IX	iktabb	NA	uktibb	yaktibb	yuktabb
reflexive of IV	X	istaktab	ask s.o. to write	ustuktib	yastaktib	yustaktab

Table 2 Active and passive participles

Form	*PART ACT*	*PART PASS*
II	mukattib	mukattab
III	mukaatib	mukaatab
IV	muktib	muktab
V	mutakattib	mutakattab
VI	mutakaatib	mutakaatab
VII	munkatib	munkatab
VIII	muktatib	muktatab
IX	muktibb	muktabb
X	mustaktib	mustaktab

forms (forms II–X), each of which typically imposes a more specific sense on that of the basic form: forms II, III, and IV are derived from form I by extension of the stem; forms V and VI are derived by prefixation of *ta-* to forms II and III, respectively. Forms VII, IX, and X involve various types of prefixation, and form VIII is derived from form I by infixation of *t* after the left-most root consonant. No consonantal root in Modern Standard Arabic has all ten verb forms, and a few verbs have one or more derived forms but lack the basic form. The prosodic template expresses the verbal form, the vocalic melody voice and aspect. The imperfect is distinguished from the perfect by imperfect person prefixes, and, in the case of form I only, by a different prosodic template. The root *k-t-b* {write} is used to illustrate verb forms in Table 1. The prototypical meaning correlates of the derived forms are listed in column two, and the specific meanings associated with the root *k-t-b*, where attested for the form in question, in column four.

The vocalic melody *a-a* indicates perfect aspect active voice, *u-i* perfect aspect passive voice, and *u-a* imperfect aspect passive voice. Excepting forms I, V and VI, the vocalic melody is *(u)-(a)-i* for the imperfect aspect active voice, and *(u)-(a)-a* for the imperfect passive. The same vocalic melodies express voice in the verbal participles, which are distinguished from the verb forms by the complementary prefixation of *mu-* to the stem. Active and passive participles from verb forms II–X are illustrated in Table 2.

Nominal Morphology

In contrast to participles from forms II–X, participles from form I verbs are derived through prosodic change: lengthening of the left-most vowel for the active participle, and of the right-most vowel for the passive participle, which also takes the complementary prefix *ma-*. Thus, *katab* 'wrote' has the participles *kaatib* 'writing; writer' and *ma-ktuub* 'written; letter.'

Finite verb stems are marked prosodically by a final light syllable – CVC, as seen in Table 1. As shown in Table 3, verbal nouns of most derived verbs (all tokens of forms IV, VII, VIII, IX, X, some of III), and a number of form I verbs, are derived from finite verbs by lengthening of the stem-final syllable to CVVC and the vocalic melody *i-a*, the inverse of the vocalic melody for the active participle. Exceptions are form II, which has a complementary prefix *ta-* and the vocalic melody *a-i*, one form III variant (*mu-kaatab-ah*), and forms V and VI, both distinguished from the finite verb by umlaut of the stem-final vowel to *-u-*.

Singular Nouns and Adjectives

In contrast to verbs, singular nouns and adjectives take a vast array of different prosodic templates and vocalic melodies. Some, such as CaCCaaC, typically used for nouns of profession (e.g., *jazzaar* 'butcher'), and the typically adjectival CaCuuC (e.g., *ḥasuud* 'envious'), and CaCiiC (e.g., *kabiir* 'big; old'), have a restricted range of meanings. Other patterns, such as CaCC, have a large range of meanings, covering human (*jadd* 'grandfather'), non-human (*kalb* 'dog'), concrete (*baḥr 'sea'), abstract (ʕaql 'intelligence'), and adjectives (ḥayy 'alive').*

Table 3 Verbal noun patterns

Form	*Verbal noun*
I	kitaab-ah

2 pl.f.	katab-tunna	t-aktub-na
3 s.m.	katab-a	y-aktub
3 s.f.	katab-at	t-aktub
3 pl.m.	katab-uu	y-aktub-uu
3 pl.f.	katab-na	y-aktub-na

Broken Plurals and Diminutives

Plurals are formed in Arabic in one of two ways: either through 'sound' plural suffixes or through the rich set of 'broken' plurals, wherein the plural is derived by mapping a portion of the singular to a plural prosodic template. McCarthy and Prince (1990a,b, 1998) have successfully analyzed broken plural derivation in moraic terms. The majority of singulars comprising three or more moras take predictable broken plural patterns. To derive the plural from such nonminimal singulars, the first two moras of the singular are mapped to an iambic template. *makaatib* 'offices' is derived from *maktab* 'office,' for example, as follows: the first two moras of the singular (*mak*) are mapped to an iambic template (*μ μμ*) to give *mμkμμ*. The vocalic melody *-a-* associates to the moraic slots to give *makaa*. The remainder of the singular (*-tab*) is suffixed to the iamb, and where this contains a vocalic slot, as here, *-i-* of the plural vocalic melody overrides the vowel of the remainder, to give *makaatib*. In the case of words comprising two moras and a number of non-minimal words, the plural cannot be predicted as easily from the singular form. Examples include *bayt* 'house' pl. *buyuut*, *bint* 'girl' pl. *banaat*, *kitaab* 'book' pl. *kutub*, *walad* 'boy' pl. *ʔawlaad*.

Whereas broken plural derivation is predictable in a proportion of cases, the diminutive is totally predictable and can, at least as far as Standard Arabic is concerned, be derived from almost any singular noun or adjective: the first two moras of the unmarked singular are mapped to an iambic template, as for the broken plural. From *walad* 'boy,' *wala* maps to *wμlμμ*. The vocalic melody *u-ai* associates to the moraic slots to give *wulai*; the remainder of the singular (*-d*) is added, to derive *wulaid* 'little boy'.

Elatives (Comparatives, Superlatives)

Elatives are derived predictably from most basic adjectives. The elative pattern is *ʔaCCaC* for triliteral roots. The vocalic melody (*-a-*) is dependent on the pattern. Examples include: *ʔakbar* 'bigger; older' (*kabiir* 'big; old'); *ʔaṣʔab 'more difficult' (ṣaʔb* 'difficult'); *ʔajban* 'more cowardly' (*jabaan* 'cowardly'); *ʔaḥsan 'better' (ḥasan 'good')*.

Inflectional Morphology

While stems are partially or wholly the product of introflection, grammatically complete words involve further affixation. Affixational elements include:

- Verbal pronominal prefixes and suffixes
- Object suffixes
- Possessive suffixes
- *-at-* feminine suffix
- Sound plurals
- Dual
- Case (nominative *-u*, accusative *-a*, genitive *-i*)
- *-n* suffix (indefinite/non-construct marker)
- Mood endings (indicative *-u*, subjunctive *-a*, jussive *-0*)

Pronominal prefixes and most suffixes, the feminine suffix, sound plurals and the dual comprise consonants and vowels, whereas all three case markers and indicative and subjunctive mood markers for the imperfect aspect are simple vowel endings. As seen in Table 4, pronominal subject markers are suffixal in the perfect aspect; in the imperfect aspect, pronominal markers are suffixal and/or prefixal. The jussive mood is given in Table 4 in the imperfect column. The indicative is expressed by suffixation of *-u* to forms ending in a root consonant (here *-b*) and suffixation of *-na* to forms ending in a vocalic suffix. The subjunctive is expressed by suffixation of *-a* to forms ending in a root consonant.

Sound Plural and Dual

Arabic has two nominal 'sound' plural suffixes: masculine and feminine. The sound feminine plural *-aat* takes the endings *-u* for nominative and *-i* for

accusative or genitive case, and, further, *-n* to express indefiniteness or non-construct, as in:

mudarris-aat-u-n
teacher-FEM.PL-.NOM-INDEF
'teachers FEM.PL'

The sound masculine plural has two main forms: nominative *-uuna* and accusative/genitive *-iina*. The dual morpheme, suffixed to masculine or feminine nouns or adjectives, also has two main forms – *-aani* for the nominative and *-aini* for the accusative/genitive case.

Arabic Linguistic Tradition

K Versteegh, University of Nijmegen, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Origin of Arabic Grammar

The beginnings of the Arabic linguistic tradition are connected with the first comprehensive account of the Arabic language, Sībawayhi's (d. circa 791) *Kitāb*. Grammar must have been practiced before his time, but the ideas of his predecessors are known only through quotations in later treatises. Basic linguistic terminology and concepts such as *qiyās* 'analogy' were developed by these grammarians, but their work did not have the scope of Sībawayhi's analysis of Arabic, which covered the entire structure of the language. The study of language probably originated in Qur'ānic exegesis. In the first two centuries of Islam, the believers needed an explanation of the text of the *Qur'ān*, which soon after the death of the prophet Muḥammad in 632 had become difficult to understand because of the large divergence between spoken language and the language of poetry and *Qur'ān*. In the earliest works on the exegesis of the *Qur'ān*, the emphasis is on the explanation of the meaning of the text, but they also contain occasional grammatical observations, for instance, about case endings and word order. Whether or not foreign influence played a role in this early stage of development is a controversial issue. According to Talmon (2003), Sībawayhi's predecessors belonged to what he calls the Old Iraqi tradition, which was based on Greek logical doctrine. Later on, this tradition was replaced by the Sībawayhian paradigm, which was to remain the authoritative source for all succeeding grammarians.

Arabic Lexicography

D El Khattab, University Hassan-II, Mohammedia, Morocco

© 2006 Elsevier Ltd. All rights reserved.

In most but not all Arabic dictionaries, the main entries are roots, which consist of basic consonants without affixes. Patterns (vowels between the consonants) give the roots different meanings in different contexts. So, for example, the root entry (ك،ت،ب) K-T-B includes the noun كتاب (*kitâb* 'book') and its plural كتب (*kutub* 'books'), the agentive noun كاتب (*kâtib* 'scribe, writer'), the verb كتب (*kataba* 'to write'), the gerund or masdar كتابة (*kitâbat* 'writing'), the adjectival perfect participle مكتوب (*maktûb* 'written'), the derivative verb استكتب (*staktaba* 'to urge someone to write'), and the derivative nouns مكتب (*maktab* 'office'), مكتبة (*maktab-at* 'library'), مكاتبة (*mukâtab-at* 'correspondence', and اكتتاب (*iktitâb* 'subscription'). In addition, all products of inflectional morphology are not treated as a subentry of the root K-T-B, but as an integral subentry under the basic verbal or nominal form.

Medieval Dictionaries

There is a rich tradition of lexicography in Arabic, going back to the 8th century C.E. Medieval Arabic dictionaries have a variety of sophisticated methods of arranging entries and writing definitions. The medieval corpus is composed mainly of poetry and the Koran.

Typology and Methods

In the Arabic lexicographical tradition, there are three types of dictionaries corresponding to three lexicographical schools:

1. phonetic dictionaries
2. alphabetic dictionaries
3. notional dictionaries.

In the first type, lexical entries are ordered according to the mode of articulation, so that for example words starting with pharyngeals such as عين (ʿ), هاء (h), حاء (ħ) are listed before words that start with the plosives velars كاف (k) and قا ف (q). This technique was first applied in معجم كتاب العين (*Kitâb al-'ayn* 'The Book of Pharyngeal Sound') of Al-Xalîl Al-Farâhîdiyy (died 776), where the consonants are arranged in the following order: pharyngeals and uvulars (ʿ, ħ, h, kh, gh), plosives velars (q, k), postalveolar fricatives (j, sh, đ), dental fricatives (ṣ, s, z), dental plosives (ṭ, t, d), labiodentals fricatives (ż, th, dh), liquids (r, l, n), labials (f, b, m), and approximants (w, â, y, '). This organization was followed subsequently by Al-Azhariyy (died 981) in تهذيب اللغة (*tahdhîb al-lugha* 'Disciplining Language'), As-ṣâħibu bnu 'abbâd (died 986) in المزهر (*Al Muzhir* 'the Flowery Book'), and Ibn Sîdah (died 1066) in المحكم (*Al Muħkam* 'The Good Dictionary'). The phonetic order of consonants following Al-Farâhîdiyy is shown in Table 1.

The second type of dictionary is characterized by the alphabetic ordering of entries. There is a conventional order of letters in Arabic, just as in the Roman alphabet. The order is shown in Table 2.

Following this classification, as one would expect, باب (*bâb* 'door') is found under باء (b), كتاب (*kitâb* 'book') is found under كاف (k), نافذة (*nâfidha* 'window') under نون (n), and so on. The main dictionaries that organize entries alphabetically according to the first letter of the word are جمهرة اللغة (*Jamhar-at al-lugha* 'Generalities in the Language') of Ibn-u Durayd (died 921), مقاييس اللغة (*Maqâyîs-u llugha* 'Patterns of Language') of Ibn Fâris (died 1004), and أساس البلاغة (*Asâs-u al-balâgha* 'The Basis of Rhetoric') of Az-Zamakhshariyy (died 1154).

Presentation of entries according to the last letter of the word is the order adopted by Al-Jawhariyy (died 1004) in الصحاح (*Aş-şiħâħ* 'The Strong Dictionary'), by Ibn Manżûr (died 1311) in his monumental work لسان العرب (*Lisân al-ᶜarab* 'The Language of the Arabs'), and by Al Fayrûzâbâdiyy (died 1418) in القاموس المحيط (*Al qâmûs-u l-muħîṭ-u* 'The Comprehensive Dictionary'). In this arrangement, words such as كتب (*kataba* 'write') and سارق (*sâriq* 'thief') are in

Table 1 The phonetic order of consonants following Al-Farâhîdiyy

Order of consonants	Some phonetic features	Letters
1	pharyngeals and uvulars	غ, خ, ه, ح, ع (ʿ, ħ, h, kh, gh)
2	plosives velars	ك ق (q, k)
3	postalveolar fricatives	ض ش ج (j, sh, đ)
4	dental fricatives	ز س ص (ṣ, s, z)
5	dental plosives	ت د، ط (ṭ, d, t)
6	labiodentals fricatives	ذ ث ظ (ż, th, dh)
7	liquids	ن ل ر (r, l, n)
8	labials	م ب ف (f, b, m)
9	appoximants	ء ي أ و (w, â, y, ')

Table 2 The alphabetic order of letters in Arabic

ـ أ ب، ت، ث، ج، ح، خ، د، ذ ر، ز، س، ش، ص، ض، ط، ظ، ع، غ، ف، ق	
ك، ل، م، ن، ه، و، ء، ي	
a, b, t, th, j, h, kh, d, dh, r, z, s, sh, ṣ, ḍ, ṭ, ẓ, ', gh, f, q. k, l, m, n, h, w, ', y	

the section for **باء** (b) and **قاف** (q), respectively. This arrangement was adopted mainly for poetic purposes, as it groups rhyming words together.

In the third type of Arabic dictionary, 'conceptual' dictionaries, entries are organized by concepts or themes, rather than by lexical units. These specialized dictionaries deal with certain selected aspects of the lexicon. For instance, there are dictionaries of concepts in particular semantic domains (animals, plants, human body parts, characters of women, religion, etc.). Among dictionaries of this type, the most important are **المخصص** (*al Mukhaşşaş* 'The Specialized Dictionary') of Ibn Sîdah , **كتاب التعريفات** (*Kitâbu tta'rîfât* 'The Book of Definitions') of Ash-sharîf Al Jurjâniyy (died 1417), and **الكليات** (*al Kulliyyât* 'Universals') of Abu l-Baqâ' Al-Kafawiyy (died 1696). The latter contains terms from the Koran and hadiths. Also relevant here is a later scientific and technical dictionary, **كشاف اصطلاحات الفنون** (*Kashshâfu ṣṭilâh-ât-i l-funûn-i* 'Discoverer of Technical Terms') by At-tahânawiyy (died 1759).

Characteristics of Medieval Arabic Dictionaries

All the medieval dictionaries mentioned above show considerable systematization at the level of form and content. The efforts of lexicographers were focused on the organization of entries (**الوضع**: *al-wad'* : 'order of entries'), on the nature of the materials (the word, the root), and on the corpus of the lexicon (**الجمع** : *al jam'*, data derived from poetry and the Koran). In addition, the dictionaries were seen as having the function of conserving the purity of the Arabic language and safeguarding against foreign (*gharîb*), introduced (*dakhîl*), obsolete (*muhmal*), and informal words (*mubtadal*).

Approaches to definitions and explanations are highly diverse. Ibn Manżûr often explains the meanings of words by their antonyms. Thus, **لعب** (*la'ib* 'game') is explained in terms of its being an antonym of **الجد** (*al-jidd* 'seriousness'). **الحرب** (*al-harb* 'war') is explained as **ضد السلم** (*didd as-silm* 'antonym of peace'); **الجدب** (*al jadb* 'drought') is explained as **نقيض الخصب** (*naqîd al khişb* 'opposite of fertility').

In other cases, the entry word is placed in a verbal or situational context. So, for example, Az-Zamakhshariyy explains meaning by giving examples of usage. He also mentions metaphorical uses. For instance, **ضرب** means 'to hit', but in the sentential context **ضرب مثلا** the verb means 'he gives an example.'

Medieval Arabic lexicographers did not feel the need to waste effort defining terms familiar to every speaker of the language. A frequent technique in *Lisân al-'arab* is use of the word **معروف** (*ma'rûf* 'well known') in place of a definition at entries such as **باب** (*bâb* 'door') and **ذهب** (*dhahab* 'gold').

Dictionaries of Contemporary Arabic

In most modern Arabic dictionaries, the basic arrangement is alphabetical order of roots, so morphological knowledge of Arabic is required to find words. For example, the speaker who does not know Arabic and who looks for the word **مكتوب** (*maktûb* 'was written') will not find it under M. It is necessary to know that **ما** (*ma-*) is a past tense passive prefix. Then one can deduce that the root under which the entry will be found is K-T-B.

There are, however, some modern dictionaries that are based entirely on alphabetical order, for example **معجم عبد النور** Abd Annour's Dictionary (1983). In this dictionary, *maktûb* is found under M. For many years, the most popular Arabic dictionary was **المنجد** (*Al-Munjid* 'The Helpful One', 1908) of Louis Ma'louf. More recently, **المعجم الوسيط** (*Al Mu'jam al waşîṭ* 'The Median Dictionary', 1972), compiled by the lexicographers of *Majma' al-lughat al-'arabiyyat* (Academy of the Arabic language, in Cairo), has presented the Arabic language in its modern perspective, focusing on contemporary usage. A feature of this dictionary is the representation of idiomatic meanings. For example, at **قتل** (*qatala* 'kill'), the idiom **قتل الشيء علما** (*qatala ash-shay'a 'ilm-an* ('he kills something in science', i.e., 'he deepens his studies') is explained. Specialized dictionaries including new words and meanings in Arabic culture also are being compiled. At a theoretical level, El Khattab (2002) describes a projected dictionary of modern Arabic that draws on the insights of modern Cognitive Linguistics.

Arabic Computational Lexicography

Arabic computational lexicography is still in the embryonic stage. Quite large corpora of Arabic text in

machine-readable form (mostly newspaper archives) are available from the Linguistic Data Consortium (LDC), the European Language Resources Association (ELRA), and other sources, but there is as yet no Arabic dictionary based on analysis of these or other electronic resources. Zemanek and others (2004) are building a treebank of parsed Arabic sentences at The Charles University in Prague. Tim Buckwalter and colleagues at the Qâmûs project (Qâmûs) are planning a corpus-based Arabic lexicon. The DIINAR-MBC research program (Dichy *et al.,* 1998) also includes work on the Arabic lexicon.

Similarly, there are no complete linguistic resources for Arabic of the kind that have been developed for English, French, and other European languages on the basis of machine-readable dictionaries. Indeed, there are still few machine-readable Arabic dictionaries. An ambitious proposal is *Arabic WordNet* (Black and El Kateb, 2004), which aims to apply the method and content of the Princeton **WordNet** project to the Arabic lexicon. The design "enables [them] to store more language-specific lexical and conceptual relations than those in the original WordNet" (according to their website).

An on-line resource worth mentioning in this connection is *Ajeeb*: an encyclopedia with a collection of medieval and contemporary dictionaries such as *Al-Qâmûs al-Muħît*, *Lisân Al-'arab*. On the same website, we also find a dictionary of English, French, and Arabic literature and a dictionary in five languages.

Arabic Linguistic Tradition

K Versteegh, University of Nijmegen, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Origin of Arabic Grammar

The beginnings of the Arabic linguistic tradition are connected with the first comprehensive account of the Arabic language, Sībawayhi's (d. circa 791) *Kitāb*. Grammar must have been practiced before his time, but the ideas of his predecessors are known only through quotations in later treatises. Basic linguistic terminology and concepts such as *qiyās* 'analogy' were developed by these grammarians, but their work did not have the scope of Sībawayhi's analysis of Arabic, which covered the entire structure of the language. The study of language probably originated in Qur'ānic exegesis. In the first two centuries of Islam, the believers needed an explanation of the text of the *Qur'ān*, which soon after the death of the prophet Muḥammad in 632 had become difficult to understand because of the large divergence between spoken language and the language of poetry and *Qur'ān*. In the earliest works on the exegesis of the *Qur'ān*, the emphasis is on the explanation of the meaning of the text, but they also contain occasional grammatical observations, for instance, about case endings and word order. Whether or not foreign influence played a role in this early stage of development is a controversial issue. According to Talmon (2003), Sībawayhi's predecessors belonged to what he calls the Old Iraqi tradition, which was based on Greek logical doctrine. Later on, this tradition was replaced by the Sībawayhian paradigm, which was to remain the authoritative source for all succeeding grammarians.

The first chapters of the *Kitāb Sībawayhi* lay down the main principles of Arabic grammar.

Principle of an Underlying Level of Analysis

In exegesis, the explanation of the text presupposed an underlying semantic level, the 'real' meaning of the text; grammarians used this principle of a level beneath the surface level of speech utterances in order to explain the grammatical form of these utterances, in particular the declensional endings. The grammarian's reconstruction of this underlying level was later called *taqdīr*, literally 'estimating, guessing', viz. of the underlying structure.

Principle of Resemblance

Linguistic elements that resemble each other come to share functions as well, or in the terminology of the Arab grammarians, they receive additional (syntactic) 'rights'. An example of the force of this principle is that of the imperfect verb. In Arabic there are two verbal forms, the perfect form *kataba*, which is regarded as indeclinable and which is combined with the pronouns of the agents, e.g, *katab-tu* 'wrote-I'; and the imperfect *yaktubu* 'he is writing', which is said to resemble the noun, since it can be used in some syntactic environments in which a participle (a nominal form) is used. This is why it receives case endings. In traditional Western grammar these are called modal endings: *yaktub-u* nominative (indicative), *yaktub-a* accusative (subjunctive) and *yaktub* apocopate, which is a special verbal case called 'jussive' in Western grammar.

Principle of Dependency

The primary aim of linguistic analysis is the explanation of the declensional endings in speech, in the nouns and the imperfect verbs. Each case-ending is thought to be the result of the action of an operator (*'āmil*), which is responsible for the change in the ending. This principle is the main operating force in all syntactic constructions. In some respects it is similar to the basic principle of modern dependency grammar (Owens, 1988: 31–88).

These three principles belong to the explanatory framework of Arabic grammar, which was never a purely descriptive discipline. The grammarian's task was to explain the forms of the language rather than simply describe them. Arabic grammar was not a normative discipline, either: since the authority of the native speaker was paramount, grammatical analysis could not prescribe any norms but had to follow the linguistic behavior of the native speaker. Obviously this native speech was an idealized principle, because after the Islamic conquests there were no more native speakers of the standard language, which had become the language of literature, religion, and administration.

The first chapters of the *Kitāb Sībawayhi* also introduce the most important categories of speech.

Division into Three Parts of Speech

Three parts of speech are recognized in Arabic grammar: noun (*ism*), verb (*fi'l*), and particle (*ḥarf*); pronouns and adjectives are counted as nouns, and so are verbal nouns and participles. Adverbs do not constitute a separate part of speech but are analyzed as nouns or particles used in adverbial phrases of time and place (*ẓarf*), a functional category. Particles are a rest category containing all indeclinable words that are not verbs, such as prepositions and conjunctions. Only verbs and particles can act as operators.

Basic Structure of the Simple Clause

Two main types of clauses are distinguished: nominal sentences, consisting of a topic (*mubtada'*) and a predicate (*xabar*); and verbal sentences, consisting of a verb (*fi'l*) and an agent (*fā'il*). The difference between these two types is formulated by Sībawayhi in purely syntactic terms. Within the framework of Arabic grammar the notion of 'subject' was not used.

Morphological Structure

Consonants are regarded as the basic carriers of lexical meaning: words consist of three or four radicals, brought together in a pattern consisting of additional consonants and vowels. These patterns are denoted with a scheme, devised by earlier grammarians, which encodes the three radicals of a words with the help of the letters *f-'-l*.

Phonological Analysis

The analysis is based strictly on the phonological shape, never on the written form. Consonants are regarded as the carriers of the semantic contents of the word, whereas short vowels indicate syntactic functions and morphological categories. Phonetically long vowels are analyzed as combinations of a vowel with a glide, thus [u:] is analyzed as /uw/, [i:] as /iy/, and [a:] as /a"/, in which /"/ indicates an abstract phonological element, called *'alif*, which serves as the related glide of the vowel *a*.

Overall, the most striking aspect of the *Kitāb* is its emphasis on linguistic form to the detriment of semantic considerations. The only exception is one chapter in the introduction in which Sībawayhi mentions the difference between homonyms and

synonyms, but he does not come back to this topic in any later chapter. Sībawayhi often refers to the intention of the speaker, which is needed to disambiguate different readings of a sentence. Semantic differences in themselves are never adduced, however, as causes for the changes in case endings, caused by the operators, and generally speaking, the semantic/pragmatic aspect of speech is more or less taken for granted.

The *Kitāb* also formed the model for the entire later tradition with respect to the question of which corpus of linguistic forms was to serve as the basis for linguistic analysis. Sībawayhi's examples stem from the collected poems of the pre-Islamic tradition, which had been handed down orally, but which were now brought together in large collections, and the text of the *Qur'ān*, which used to be transmitted orally as well, but which was codified under the first successors of the prophet Muḥammad after his death.

Because of Sībawayhi's reliance on a written corpus of speech, which formed the basic legitimization of the accuracy of his grammatical explanation, his grammar was synchronic in nature. The underlying level reconstructed by the grammarian for the purpose of elucidating the structure of the actual utterances does not have any diachronic dimension. From the earliest period of the expansion of Arabic during the Arab conquests in the 7th century, there was a large divergence between spoken and written language, similar to the present-day diglossia in the Arabic-speaking world. The grammarians only recognized the classical Arabic language (*fuṣḥā*), codified in the *Qur'ān* and poetry, as the legitimate object of linguistic research, and this form of the language was regarded as unchanging.

The vernacular languages (*'āmmiyya*), often called 'Arabic dialects', were ignored completely by the grammarians. It is true that there was a special genre, called *laḥn al- 'āmma* 'errors of the common people', but significantly these treatises do not deal with the structural differences between the spoken and the written language, but with the mistakes semi-literates make when they attempt to write classical Arabic. In general historical writings complaints about the 'corruption of speech' – even in the mouths of the Bedouin who are generally considered to be the purest speakers of classical Arabic – are a common topos, but there is no reflection of this in grammatical literature, which continued to operate with the fiction of a pure language, spoken by native speakers.

Organization of Grammar

The best way to illustrate the organization of Arabic grammar is by listing the contents of Sībawayhi's *Kitāb*. Although the text of the *Kitāb* is sometimes opaque (possibly because of the bad state of the existing editions, which do not reflect the text in the majority of the manuscript tradition, cf. Humbert 1995) and suffers from a certain terminological ambiguity, we have a rather clear picture of Sībawayhi's ideas and are in a position to compare it with the collected views of later grammarians. There is some truth to the saying that the entire tradition is nothing but a commentary on the *Kitāb*, since the basic presuppositions of the *Kitāb* remained on the whole unchallenged.

The *Kitāb* deals first with syntax, then with morphology, and finally, as an appendix, with phonological/phonetic issues. Most later grammars follow this order, with only slight variations. Some later grammarians took the subdivision into nouns, verbs, and particles as the basis for their descriptions, but even grammatical treatises for beginners usually follow Sībawayhi's order. In accordance with the dependency principle, the use of declensional endings was part of the syntactic treatment.

The first section is on syntax and discusses the following topics:

- accusative of the object, 8–42
- implicit operators, 50–60
- accusative of situation (*ḥāl*), 61–131
- topicalization (*ibtidā'*), 132–140
- accusative of specification (*tamyīz*), 141–145
- accusative in vocative clauses (*nidā'*), 146–174
- accusative after absolute negation, 175–184
- accusative in exceptive clause, 185–202
- pronominal forms, 203–232.

These chapters deal with verbal operators, which cause an accusative ending in the words upon which they operate. The remainder of the syntactic section deals with particles as operators:

- particles of the subjunctive, 233–244
- conditional sentences, 245–254
- complementizers, 261–276
- disjunctive sentences, 277–284.

The second section is on morphology. Sībawayhi's main concern is the establishment of the radical structure of the words. The following topics are dealt with:

- diptotic and triptotic words, 285–315
- relational adjectives, 318–341
- dual and plural, 343–355
- diminutives, 359–396
- broken plurals, 416–431
- verbal morphology, 432–476.

The chapters on diptotic and triptotic words deal with an idiosyncratic feature of Arabic grammar, the

merger of two case endings in some categories of nouns: for instance, proper names of foreign origin. In the remaining chapters on morphology, the emphasis is on those morphological patterns that are important for the reconstruction of the radical structure, for instance, on the formation of the diminutive, which crucially depends on the distinction between radical consonants and so-called additional consonants (*ḥurūf zā'ida*).

From chapter 477 on, the emphasis is on (morpho-) phonological and phonetic phenomena.

- *'imāla*, 477–482
- pausal forms, 490–500
- nominal patterns, 511–525
- weak verbs, 531–558
- reduplication, 559–564.

In these chapters the emphasis is on the phonetic changes affecting words. In the case of the *'imāla*, this is the raising of the vowel /a/, which is constrained by the category of the word. Likewise, pausal changes depend on the category of the word involved. The chapters that follow deal with changes that are caused by the presence of a weak consonant in the word. The behavior of the nouns and verbs with weak radicals is again an example of the importance of the tri-radical structure: if one of the radicals is a weak consonant, i.e., a glide (*w*, *y*, *'alif*), the surface structure of the word often exhibits only two radicals, occasionally only one. In the weak verbs **qawama* 'he stood up', **sayara* 'he rode', the combination of vowels and glides leads to a change /qa:ma/, /sa:ra/, which obliterates the middle radical; these forms are realized phonetically as [qa:ma], [sa:ra]. Grammarians treat the phonological reconstruction as underlying forms: later grammarians emphasized the fact that these were abstract reconstructions by the grammarian, not historically attested forms. The place of these chapters at this point of the *Kitāb* can be explained by the different behavior of the weak consonants in nouns and verbs.

The final chapters in this part deal with reduplication, not as a phonological phenomenon but as a feature of a number of roots containing identical second and third radicals, which are subject to a constraint against CvCv# sequences, so that a word like **radada* 'he returned, replied' changes into *radda*.

- phonetic issues, 565–574.

Strictly speaking, the phenomena studied in these chapters are not connected with morphology or syntax, and given the constraints within which the grammarians worked, they may seem on the surface not to contain any linguistically relevant information. Yet, closer examination reveals that issues such as assimilation and phonetic differences between the pre-Islamic dialects are relevant after all since these may lead to apparent exceptions to the rules – and besides, they may obscure the radical structure of the word.

Linguistics and Other Disciplines

Linguistics was regarded by the Arabs as an autonomous discipline in its own right. The extensive Arabic biographical literature lists the names of thousands of grammarians and the titles of their writings, together with anecdotes about their professional activities. The term used for this discipline is *naḥw* 'grammar', which was the domain of the *naḥwiyyūna* 'grammarians'. The term is also used to designate one of the two subsections of grammar, which in Western linguistics is called 'syntax', the other subsection being *ṣarf* 'morphology and morphophonology'. Grammar was distinguished from lexicography (*luġa*). Even though most grammarians also worked as lexicographers and vice versa, it was perfectly normal for someone to be excellent in one and weak in the other. Syntax and morphology, on the other hand, were more like subdomains of one discipline. As a matter of fact, although there are special treatises on syntax and morphology, most grammarians treated them together.

Traditionally, grammar and the study of poetry were a normal component of an intellectual's education, and most scholars at one stage followed lessons of a grammarian. Nonetheless, being a grammarian was not regarded as a profession in the same way as, for instance, being a theologian or legal expert was. As a rule, grammarians did not teach at universities, but worked as private teachers, living on the income they received for their lessons and often having a main job elsewhere, for instance, as a lawyer or a bookseller.

After the initial close connection between grammar and Qur'ānic exegesis, the two sciences drifted apart. In most introductions to grammatical treatises, grammarians paid lip service to the use of grammar for religious purposes, and grammar continued to be one of the *'ulūm 'islāmiyya* 'Islamic sciences', but in practice, linguistics was often studied for its own merits. The status of linguistics as one of the Islamic sciences was threatened by the introduction in the Islamic world of Greek logic and philosophy in the 9th and 10th centuries, when logicians and philosophers alike asserted that the study of meaning was their domain, which meant that the grammarians ought to confine themselves to the study of the form of the words. This led to a lively debate in the Arab world about the proper place for the foreign sciences, which

eventually were relegated to a separate category, that of the Greek sciences (*'ulūm yūnāniyya*). Grammar then resumed its customary position as ancillary to the study of the *Qur'ān*.

Some grammarians of this period attempted to reconcile grammar and logic by introducing logical methods in grammar. These grammarians were accused of 'mixing grammar with logic', although their works do not exhibit a great divergence from traditional grammar as it had been practiced since the days of Sībawayhi. It is true, though, that they took greater care to formulate explicit definitions and to arrange their works in a formal fashion. In this respect they differed from their predecessors, who had a tendency to use terms and notions without properly defining them, thus causing a certain ambiguity in their terminology.

The introduction of logic also affected the selection of topics that grammarians dealt with. In 10th-century writings, new questions were asked about the internal structure of language, the relationship between language and thought, and the origin of language. Because of the obvious connection with religious ideas, the topic of the origin of language was heavily debated for some time by linguists and theologians alike, but after the 10th century, this topic disappeared from the domain of linguistics. Almost all grammarians agreed that the question could not be solved by human beings, and it was therefore useless to discuss it.

After the initial period linguistics became an increasingly technical discipline. The traditional link with poetry became looser, and technical discussions on fine points of linguistic structure came to replace the connection with literature and style. From the 10th century on, some linguists attempted to reestablish this link by focusing on the semantic side of language. They asserted that linguistics had become overly focused on formal matters, thereby neglecting the semantic side of language. In this period efforts were made to establish a new link between the formal and the semantic sides of language. In one such scheme, the sciences of language are subsumed under the heading *'ilm al-'adab* 'science of literary culture', which is subdivided into the linguistic sciences of *naḥw* 'grammar' and *ṣarf* 'morphology', and the semantic sciences *'ilm al-ma'ānī*, roughly equivalent to rhetoric and stylistics, and *'ilm al-bayān*, roughly equivalent to the study of metaphorical language (Simon, 1993).

The original connection between linguistics and Qur'ānic exegesis was reestablished in a new paradigm that grew out of the *'ilm al-ma'ānī*, the main interest of which was in the pragmatic aspect of speech and its consequences for legal argumentation. This science was called *'uṣūl al-fiqh* 'the principles of law', even though its main thrust was linguistic in nature. Within this discipline the extensional and intensional meaning of speech was studied in order to establish the relationship between words and their denotata (Weiss, 1966).

Use of the Arabic Model for Other Languages

Arab grammarians hardly ever showed any interest in the structure of other languages. Apart from occasional references to the absence of certain traits in other languages, intended to demonstrate the superiority of Arabic (e.g., the absence of declension, or the uniqueness of certain Arabic consonants, supposedly lacking in the phonemic inventory of other languages), these languages were neither described nor compared with Arabic. Unlike the Hebrew grammarians, the Arabs apparently were not aware of the relatedness of the Semitic languages. Unless they were native speakers of other languages, most of them probably did not know any foreign languages. Sībawayhi himself likely spoke Persian as his first language, but he does not exhibit any interest in comparing that language with Arabic.

Not even the introduction of Greek logic in the 9th and 10th centuries brought any change in this disinterest: notwithstanding the universalist claims of the representatives of the new fashion of Greek logic, the acquaintance with Greek philosophy and logic was not accompanied by any curiosity about the structure of the Greek language, in spite of the presence of a considerable number of translators who knew not only Greek, but usually also Syriac. As for the Arab philosophers themselves, they were keenly interested in the difference between the two languages, pointing out, for instance, the absence of a copula like the Greek verb *éstin* in Arabic; they may even have had some understanding of the Greek grammatical tradition.

The only grammarian in the Arab tradition who is known for his interest in foreign languages is an Andalusian grammarian, 'Abū Ḥayyān al-ġarnāṭī (d. 1345). While in Egypt, he wrote a number of works about the language of the Turkic-speaking Mamluks who at that time were the rulers of Egypt. His approach is exactly the same as in his works on Arabic, but he has a keen eye for the difference between the two languages. One of the most interesting aspects of this analysis is the fact that he denies the presence of declensional endings in Turkic. The case endings that Western grammars distinguish in Turkic, for instance for the locative and the dative, are analyzed by him as *'alāmāt* '(semantic) markers'.

In Arabic grammar the term 'markers' is also used, for instance, to indicate the feminine ending *-t*. This means the semantic cases of Turkic are analyzed differently from the syntactic cases of Arabic. In terms of the Arab grammarians, there is no real declension since the endings are not assigned by an 'operator' (*'āmil*), which is a condition for declensional endings.

'Abū Hayyān's was not the only attempt to describe a foreign language with the help of the Arabic model, though he was the only one whose mother tongue was Arabic. After him, many treatises about the Turkic language were written by native speakers of Turkic. These authors follow his example in describing the Turkic language by using the categories of the Arabic grammatical model, for instance, by axiomatically assuming that Turkic, too, possessed three parts of speech, and by assuming that the formalism to describe word structure in Arabic with the help of the three radical system of *f-'-l* was also suitable for the description of Turkic (Ermers, 1999).

The analysis of Syriac by the Syrian grammarians is an interesting case of influence and counter-influence. In its formative period, Arabic grammar probably profited from the experience of Syriac grammarians, who based their analysis on the translation of Dionysios Thraxs' *Tékhnè*. The Arab grammarians probably borrowed from them the names of the vowels and the case endings. But later, in the 11th through 13th centuries, when Syriac had become a minority language in the Islamic empire, Syriac grammarians borrowed a new set of linguistic terms and notions from Arabic.

In Egypt, the speakers of Coptic never possessed a grammatical tradition of their own for the description of their language. After the conquest of Egypt in the 7th century, the Coptic language was soon replaced by Arabic, although it remained in use only for religious purposes in the Coptic church. In the 13th and 14th centuries however, a number of Coptic authors decided to adapt the Arabic grammatical framework for grammatical introductions to the Coptic language, written in Arabic (Bauer, 1972).

The grammar of Hebrew, too, was elaborated within the framework of Arabic linguistic theory. Building on the Hebrew exegetical tradition, the Hebrew grammarians borrowed the framework of Arabic grammar in order to analyze their holy language (Zwiep, 1995). Their treatises were usually written in Arabic, the mother tongue of the Jews in the Islamic empire. Some of them introduced the principle of tri-radicalism into Hebrew, even though the tri-radical structure is much less transparent in that language than in Arabic. In one respect the Hebrew grammarians differed from their Arabic model: they actively engaged in the comparison of Hebrew with other Semitic languages. Long before the advent of historical comparative linguistics in the 19th century, the Hebrew grammarians were already aware of the systematic relationship between the most important Semitic languages.

After the conquest of the Persian Empire, the Persian language had at first become marginalized, but in the 10th century a modern variety of the language was revived for cultural purposes at the court of the Persian dynasties, and it became the language of poetry again. The revival of Persian also led to a renewed interest in the language. For their study of the Persian language, Persian grammarians used the terminology of Arabic grammar. Their main interest was in lexicography, but in connection with this activity they also wrote grammatical treatises. One of the problems the Persian grammarians had to deal with in their attempts to adapt the Arabic model to the structure of Persian was the fact that Persian as an Indo-European language uses suffixes and prefixes rather than morphological patterns of the Semitic type. In order to accommodate such a different structure, Arabic terms like *ḥarf zā'id* 'additional consonant' came to be used in a derived sense (Jeremiās, 2000).

In the west of the Arab world, the Berber languages had never been completely replaced by Arabic. Berber remained a primarily spoken language, but after the 12th century a Berber literature arose, especially in the Sous. Arabic treatises were translated into Berber and original writings were composed in Berber, using Arabic script. The Arabic language was studied intensively, accompanied by the sporadic publication of grammatical notes about the Berber language, chiefly of a lexicographical nature (van den Boogert, 1997: 113–119). Naturally the Arabic tradition with which these scholars were familiar provided the framework to do so.

Outside the Arab world, wherever Arabic culture and literature were brought together with Islam, an Islamic book culture emerged, written in indigenous languages, but in Arabic script. In the process of transmission of Islamic knowledge, these languages borrowed a large number of Arabic words. Thus, for instance, in Southeast Asia, a special literary genre arose, sometimes called Kitap Malay, in which Arabic loanwords were introduced by the dozens. Most of this literature was in the field of theology or Islamic law, but in some cases the system of Arabic grammar was used to analyze the indigenous language. In the 19th century several Malay grammars appeared in which the language was analyzed with the help of Arabic terminology (Kapteijn, 2000).

The introduction of western science at the end of the 19th century meant the end of the indigenous

tradition in the Islamic world. Even though treatises in the traditional framework continued to be written in Arabic, the practice of linguistics at the university level came to be dominated by the prevalent trends in western linguistics, especially in Morocco and Egypt. In pre-university education, there was a drive to reform the old-fashioned grammatical system. Some linguists and teachers tried to remedy the deplorable state of education in classical Arabic by replacing the traditional grammatical system with newer categories and terminology, including the introduction of such categories from Greco-Latin school grammar as 'subject' and 'predicate'. One point that was particularly abhorrent to the reformers was the pervasive notion of 'operator' (*'āmil*), which became associated with the most sterile forms of Arabic grammar, in which the only issue had become the identification of the *'āmil* in increasingly complicated sentences. However, since the old terminology was often retained, the resulting hybrid system in teaching often suffered from a lack of consistency.

Aramaic and Syriac

Origin and Expansion

Aramaic is the native name of a language that first manifests itself in inscriptions in Syria early in the 1st millennium B.C. but that in subsequent centuries, during the period of the Assyrian and Persian empires, was widespread throughout the Near East and is found as far afield as Egypt, Cilicia, and Iran. Following the conquests of Alexander the Great, and during the subsequent eras of Macedonian and Roman influence, it co-existed with Greek as a principal medium of written communication over this wide area. The conquest of the region by the Arabs in the 7th century A.D. eventually brought its dominant position to an end, but it remained significant for many years thereafter as a spoken and, especially, a literary language. Greek writers designated it Syriac, a term derived from *Assyrian*, and the Greek name was frequently preferred over the native one by Aramaic-speaking Jews and Christians, among whom *Aramaean* became a designation for their pagan neighbors. Over time, Aramaic developed a number of clearly distinct literary dialects, each evolving out of a local form of the language, and these were extensively employed by Jewish, Christian, and other religious communities. In contemporary usage, Syriac usually refers to the principal literary dialect employed by Christians, whereas Aramaic is retained as a generic term for the whole group. Spoken forms of the language have survived to this day among the religious communities that have preserved it in their liturgies and in a few places as an everyday language.

Aramaic belongs to the Semitic group of languages and, more particularly, to the northwest branch, which, according to prevalent opinion, contained in the 1st millennium B.C. two distinct strands, Canaanite (which includes Hebrew and Phoenician) and Aramaic. Despite its extensive use in the Assyrian and Persian empires, it has left few literary or epigraphic remains from these periods, although those that have survived are of considerable importance in the study of the history of the region and fresh discoveries are steadily adding to the stock. In the Hellenistic and Roman periods, the material becomes more abundant, and, especially from the 4th century onward, a large body of Christian literature is preserved in Syriac and a substantial body of Jewish literature in Palestinian and Babylonian Aramaic dialects. Smaller extant corpora in dialects employed by the religious communities in question stem from the Mandaeans, the Samaritans, and Syro-Palestinian Christians who adhered to the Orthodox confession of the Byzantine emperors.

Phases and Dialects

Over the 3000 years of its recorded history, the language has naturally undergone many developments. Three broad phases are easily discernible. In the first, represented mainly in inscriptions and papyri, the form of the language is surprisingly uniform, and the differences between documents from diverse times and places are relatively minor. In the second, represented in the literature (beginning in the 4th century A.D. or earlier) of Jews, Christians, Samaritans, and Mandaeans, more marked dialectal differences are apparent, with two broad groupings. The eastern group, of Mesopotamian provenance, comprises Syriac, Jewish Babylonian Aramaic, and Mandaic; the western group comprises Jewish Palestinian Aramaic, Samaritan, and Syro-Palestinian Christian Aramaic. A third phase of modern eastern and western dialects can be discerned from approximately the 17th century. Further differentiation beyond these three is less clear cut, but in recent years a fivefold classification has gained considerable support, with the period prior to the emergence of the literature in the eastern and western literary dialects divided into three. The distinction between the earliest of these, Old Aramaic, and its successor is relatively unproblematic. Old Aramaic inscriptions belong to the period of the independent Aramaean states (10th–8th centuries B.C.) and exhibit a number of distinctive grammatical features, some of them similar to those known in Canaanite. Texts in Aramaic from the subsequent period come from a vastly greater area, but despite their wide geographical and chronological range they exhibit a high degree of homogeneity. Many of them are administrative in nature, and the language in which they are composed was evidently employed as a formal means of communication in much of the Assyrian, Babylonian, and Achaemenid empires. Its adoption by the imperial chancelleries (a striking example of which is the presence of Aramaic ideograms in Pahlavi texts) is no doubt the reason for the high degree of standardization, and this phase is therefore commonly designated Official Aramaic. More problematic is the characterization of the Aramaic material originating between the end of the Achaemenid Empire and the beginnings of the extensive literature in the later Jewish dialects and classical (Christian) Syriac. In this period (roughly 200 B.C–200 A.D.), several different dialects emerge in a number of localities. These include

Palmyrene, Nabataean, Hatran, and Old Syriac (Edessan) inscriptions, and inscriptions and fragments of literary works from Palestine. Although all these dialects are quite similar to Official Aramaic and developed out of it, the influence of spoken local dialects or other languages (Arabic among the Nabataeans and Akkadian in Mesopotamia) led to a fragmentation and modification of the earlier fairly uniform Official Aramaic. In none of these areas, however, do we have evidence this early of the emergence of a vigorous or widespread new literary Aramaic. Although some scholars therefore consider this period as still belonging to the literary phase of Official Aramaic, others are sufficiently impressed by the differences to classify it as a new phase, Middle Aramaic, falling between Official Aramaic and the Later Aramaic of rabbinical Jewish and Christian Syriac literature. The expansion and consolidation of these religions was presumably responsible for the transformation of local dialects into significant and widespread means of literary expression.

Dialects and Religious Communities

The Aramaic inscriptions of Old, Official, and Middle Aramaic provide important information on deities worshipped in Syria and Mesopotamia in pre-Christian and early Christian times. Papyri from Egypt constitute the largest body of material in Official Aramaic, among which those of a Jewish military colony at Elephantine are of particular interest for the light they shed on the religious beliefs and practices of this group of Jews in the Achaemenid Empire. The language of the Aramaic sections of *Ezra* and *Daniel* also belongs to Official Aramaic and differs only slightly from that of the Elephantine papyri. Subsequent Jewish writings and inscriptions of Palestinian provenance belong to the Middle Aramaic phase and include fragments of a number of literary works preserved among the Dead Sea Scrolls. The problem of determining the form of spoken Aramaic current in 1st century A.D. Palestine has attracted much attention on account of its relevance to New Testament studies. Although the literary and epigraphic material from the period is consistent with the use of Middle Aramaic, the extant material is still fairly sparse, and some scholars still hold (as did most of those of earlier generations, to whom Middle Aramaic was unknown) that the Palestinian dialects of later rabbinical literature are a valuable source for the reconstruction of the spoken language of the 1st century A.D.

The rabbinical literature in Jewish Palestinian Aramaic comprises various Targumim (paraphraistic Aramaic versions of sections of the Hebrew Bible), Midrashim (commentaries on the biblical books), and parts of the Palestinian Talmud. The latter two are written partly in Hebrew and partly in Aramaic. The Targum on the Pentateuch attributed to Onkelos and that on the *Prophets* attributed to Jonathan were used in Babylonia and, unlike the Palestinian Pentateuch Targum, do not therefore represent a purely Palestinian form of Aramaic. Jewish Babylonian Aramaic is represented in the Aramaic sections of the Babylonian Talmud and in the Responsa literature of the 8th–10th centuries A.D., the replies of the heads of the Babylonian academies to legal questions from scattered Jewish communities. The famous 13th century mystical work from Spain known as the *Zohar* is also written partly in Hebrew and partly in an artificial Aramaic. Samaritan Aramaic is represented principally by the Samaritan Targum to the Pentateuch and the theological treatise known as *Memar Marqah*, an important source for the knowledge of Samaritan religion. The language of the Mandaean texts is Eastern Aramaic, but linguistic as well as historical arguments have been advanced in favor of a Palestinian origin contemporary with the beginnings of Christianity. Because, however, these are not decisive, and the Mandaeans are only known in Iraq and further east, a Mesopotamian origin of the religion and the texts is still widely accepted.

The largest extant corpus of Aramaic literature is that in Syriac. Originally the local dialect of Edessa (modern Urfa), Syriac was adopted as a literary language by Christians throughout the Near East. Once adopted, it remained remarkably stable in most respects, although two slightly differing dialects (eastern and western, using different scripts and differing in the pronunciation of some vowels) emerged around the 5th century. These were associated respectively with the East Syrian Church (in Sasanid domains) and the Syrian Orthodox Church (in the Roman domains). Syriac-speaking Christians were active in the translation of Greek writings into Syriac, not only the Bible and Greek patristic writers but also (from the 6th century) medicine (Galen) and logic (Aristotle). Their expertise in these secular subjects in the period of the ʻAbbasid caliphate, and their ability to read both the relevant Greek texts and the earlier Syriac translations of them, stimulated Muslim interest in these subjects and led to the Syrians being in great demand as translators from Greek to Arabic, such translations being frequently done through a Syriac intermediary. Greek loanwords, grammatical forms modeled on Greek, and Greek syntax all greatly influenced Syriac, increasingly so from the 6th century. By contrast, the influence of Arabic on the literary language was slight. In the earlier period, the most striking literature in Syriac

is the religious poetry of Saint Ephrem, which was much admired and imitated even beyond the Syriac language area. From the 10th century, Arabic replaced Syriac among Christians as the chief language of theology, philosophy, and medicine, but the 13th century saw a veritable West Syriac renaissance, embodied especially in the great polymath Bar Hebraeus, who wrote with equal facility in Syriac and Arabic. In contrast to the wide use of Syriac, Syro-Palestinian Christian Aramaic (alternatively designated Syro-Palestinian Syriac because it was written in the West Syriac script) was employed only in Palestine and Syria, and the extant texts (mostly biblical, liturgical, or hagiographical) are all translations from Greek.

Spoken Aramaic dialects have been in continuous use in a number of places right into modern times. Modern Western dialects of Aramaic are spoken, by Christians and Muslims, in three villages north of Damascus, namely Ma'lula, Bah'a, and Jubb 'Addin. Eastern dialects have been more extensively used by Christians in various localities. In the mountainous area of Southeast Turkey known as Tur 'Abdin, Turoyo ('the mountain language') is spoken by members of the Syrian Orthodox Church. Other Eastern Aramaic dialects have been spoken in modern times by the Jews of Kurdistan and Azerbaijan, most of whom have now emigrated to Israel, and a modern Mandaic dialect has survived in Iran. The greatest use of Aramaic in modern times, however, has been by East Syrian Christians, among whom a number of East Aramaic dialects have been employed. Modern literary Syriac (Swadaya) may be said to have begun with the printing of books in the local dialect by the American Presbyterian Mission at Urmia in Northwest Iran. Although the number of people currently using some form of Aramaic is small, their determination to keep it alive is a testimony to their pride in a language whose demonstrable lifespan extends to 3000 years.

Arawak Languages

A Y Aikhenvald, Institute for Advanced Study, La Trobe University, Bundoora, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Arawak language family contains the largest number of languages in Latin America. Geographically, it spans four countries of Central America – Belize, Honduras, Guatemala, Nicaragua – and eight of South America – Bolivia, Guyana, French Guiana, Surinam, Venezuela, Colombia, Peru, Brazil (and also formerly Argentina and Paraguay).

There are about 40 living Arawak languages. The first Native American peoples encountered by Columbus – in the Bahamas, Hispaniola, and Puerto

Rico – were the Arawak-speaking Taino. Their language became extinct within a hundred years of the invasion. Spanish and many other European languages inherited a number of loans from Arawak languages. These include widely used words such as *hammock*, *tobacco*, *potato*, *guava,* and many other names for flora and fauna.

The creation of a mixed language of Arawak/Carib origin in the Lesser Antilles is one of the most interesting pieces of evidence on language history in preconquest times. Speakers of Iñeri, a dialect of the Arawak language now (misleadingly) called Island Carib, were conquered by Carib speakers. They developed a mixed Carib/Arawak pidgin that survived until the 17th century (Hoff, 1994). Speech of men and speech of women were distinguished in the following way. Women used morphemes and lexemes of Arawak origin, while men used lexical items of Carib origin and grammatical morphemes mostly of Arawak origin. The pidgin coexisted with Carib used by men and Iñeri used by women and children; it belonged to both parties and served as a bridge between them. This diglossia gradually died out with the spread of competence in Island Carib among both men and women. As a result, Island Carib, an Arawak language, underwent strong lexical and, possibly, grammatical influence from Carib.

The languages in areas settled by the European invaders soon became extinct. Those on the north coast of South America perished first, before 1700. When the search for gold and rubber extended up the Amazon and its tributary the Rio Negro, further languages succumbed, from the 18th century up until the present day. Sometimes the Indians retaliated, attacking settlements and missions; but the invaders always returned. Indian rebellions often provoked forced migrations which sometimes ended up creating a new dialect or even a language. For instance, in 1797 the British authorities removed the rebellious inhabitants of St. Vincent (an island in the Lesser Antilles) to Belize on the mainland. These were racially a mixture of black slaves and Indians, who spoke Island Carib. This resulted in the creation of a new dialect of Island Carib – known as Central American Island Carib, Kariff, Black Carib, or Garifuna – which by the 20th century had developed into a separate language, now spoken in Central America (Taylor, 1977).

The overwhelming majority of Arawak languages are endangered. Even in the few communities with more than 1000 speakers, a national language (Portuguese or Spanish) or a local lingua franca (Lingua Geral Amazônica, Quechua, or Tucano) is gaining ground among younger people. The few healthy Arawak languages are Guajiro in Venezuela and Colombia (estimates vary from 60 000 to 300 000 speakers) and the Campa languages (total estimate 40 000 to 50 000 speakers), one of the largest indigenous groups in Peru.

Most of the materials on Arawak languages collected during the second half of the 20th century are by missionary linguists. Their quality and quantity varies. Only three or four languages have full descriptions available.

The genetic unity of Arawak languages was first recognized by Father Gilij as early as 1783. The recognition of the family was based on a comparison of pronominal cross-referencing prefixes in Maipure, an extinct language from the Orinoco Valley, and in Moxo from Bolivia. Gilij named the family Maipure. Later, it was renamed Arawak by Daniel Brinton after one of the most important languages of the family, Arawak (or Lokono), spoken in the Guianas. This name gained wide acceptance during the following decades. The majority of Native South American scholars use the name Arawak (Aruák) to refer to the group of unquestionably related languages easily recognizable by pronominal prefixes such as *nu-* or *ta-* 'first person singular', *(p)i-* 'second person singular', prefix *ka-* meaning 'have', and negator *ma-*. A number of scholars, mainly North Americans, prefer to use the term Arawak(-an) to refer to a much more doubtful higher-level grouping, and reserve the term Maipuran (or Maipurean) for the group of undoubtedly related languages that are claimed to be one branch of Arawakan (see Payne, 1991). Here I follow the South American practice and use the name *Arawak* for the family of definitely related languages.

The limits of the family were established by the early 20th century. Problems still exist concerning internal genetic relationships within the family and possible genetic relationships with other groups. Reconstruction, internal classification, and subgrouping of Arawak languages remain matters of debate; further detailed work is needed on both the descriptive and comparative fronts.

The putative studies of Arawakan by Ester Matteson, G. Kingsley Noble, and others are deeply flawed. Unfortunately, these have been adopted as the standard reference for the classification of Arawak languages, especially among some anthropologists, archaeologists, and geneticists, influencing ideas on a putative proto-home and migration routes for proto-Arawakan' – see the criticism in Tovar and De Tovar (1984), Dixon and Aikhenvald (1999: 12–15), and Aikhenvald (1999a).

Little is known about a proto-home for the Arawak family. The linguistic argument in favor of an Arawak proto-home located between the Rio Negro and the Orinoco rivers – or on the Upper Amazon – is based on the fact that there is a higher concentration of structurally divergent languages found in this region.

This area has also been suggested as one of the places where agriculture developed. This is highly suggestive and corroborated by a few mythical traditions of northern origin by Arawak-speaking peoples south of the Amazon. The origin myths of the Tariana, in northwest Amazonia, suggest that they could have come from the north coast of South America.

Arawak languages are complicated in many ways. Words can be differentiated by stress in some languages, such as Baure and Waurá (south of Amazonas), and Tariana, Achagua, and Warekena (north of Amazonas). At least two have tones – Terêna in the South, and Resígaro spoken in the far northeast of Peru.

Each Arawak language has a few prefixes and numerous suffixes. Prefixes are typically monosyllabic, while suffixes can consist of one or more syllables. Roots usually contain two syllables. Prefixes are rather uniform across the family, while suffixes are not. What is a free morpheme in one language can be a grammatical marker in another language; for instance, postpositions become causative markers, and nouns become classifiers. An Apurina noun *maka* means 'clothing' – this is where the word for hammock comes from. In Baniwa of Içana, *-maka* is a classifier for stretchable thin extended objects, e.g., *tsaia* 'skirt' or *dzawiya* 'jaguar's skin', as in *apa-maka* (one-CLASSIFIER:CLOTHING) 'one piece of clothing'.

Most grammatical categories in Arawak languages are verbal. Cases to mark subjects and objects are atypical. Tariana, spoken in northwest Brazil, has developed cases for core grammatical relations to match the pattern in nearby Tucanoan languages (Aikhenvald, 1999b).

Arawak languages spoken south of the Amazon (South Arawak) have a more complex predicate structure than those north of the Amazon (North Arawak). South Arawak languages such as Amuesha or Campa have up to thirty suffix positions. North Arawak languages such as Tariana or Palikur have not more than a dozen suffixes. Suffixes express meanings realized by independent words in familiar Indo-European languages, e.g., 'be about to do something', 'want to do something', 'do late at night', 'do early in the morning', 'do all along the way', 'in vain', 'each other'.

Verbs are typically divided into transitive (e.g., 'hit'), active intransitive (e.g., 'jump') and stative intransitive (e.g., 'be cold'). All Arawak languages share pronominal affixes and personal pronouns. Pronominal suffixes refer to subjects of stative verbs and direct objects. Prefixes are used for subjects of transitive verbs and of intransitive active verbs, and for possessors. That is, most Arawak languages are of active-stative type. For instance, in Baniwa one says *nu-kapa* 'I see' and *nu-watsa* 'I jump', but *nu-kapa-ni* 'I see him' and *hape-ni* 'he is cold' (*nu-* refers to 'I' and *-ni* to 'him'). And 'my hand' is *nu-kapi*.

Table 1 Pronominal prefixes and suffixes in proto-Arawak

Person	*Prefixes*		*Suffixes*	
	Singular	*Plural*	*Singular*	*Plural*
1	*nu- or ta-*	*wa-*	*-na, -te*	*-wa*
2	*(p)i-*	*(h)i-*	*-pi*	*-hi*
3nf	*r i-, i-*	*na-*	*-r i, -i*	*-na*
3f	*thu-, ru-*	*na-*	*-thu, -ru, -u*	*-na*
'impersonal'	*pa-*	—	—	—

Some languages have lost the pronominal suffixes (and with them the morphological basis for an active-stative system); these include Yawalapiti (Xingú area, Brazil) and Chamicuro (Peru) to the south of the Amazon, and Bare, Resígaro, Maipure, and Tariana to the north. The form of the first person pronoun is *ta-* in the Caribbean (Lokono, Guajiro, Añun, Taino) and *nu-* in other languages. This is the basis for classification of Arawak languages into *Nu*-Arawak and *Ta*-Arawak.

Proto-Arawak must have had an unusual system of four persons: first, second, third, and impersonal. The forms of prefixes and suffixes reconstructed for proto-Arawak are given in Table 1.

Most Arawak languages distinguish two genders – masculine and feminine – in cross-referencing affixes, in personal pronouns, in demonstratives, and in nominalizations, e.g., Palikur *amepi-yo-* 'thief (woman)', *amepi-ye* 'thief (man)', Tariana *nu-phe-ri* 'my elder brother', *nu-phe-ru* 'my elder sister'. No genders are distinguished in the plural. The markers go back to proto-Arawak third person singular suffixes and prefixes: feminine *(r)u*, masculine *(r)i*. Some languages also have complicated systems of classifiers – these characterize the noun in terms of its shape, size, and function (Aikhenvald, 1999a). For instance, Tariana and Baniwa of Içana have more than 40 classifiers which appear on numerals, adjectives, verbs, and in possessive constructions. Palikur has more than a dozen classifiers which have different semantics and form depending on whether they are used on numerals, verbs, or on adpositions (Aikhenvald and Green, 1998). Pronominal genders have been lost from some languages, e.g., Terêna, Amuesha, Chamicuro, Pareci, Waurá (south of the Amazon), and Bahwana (north of the Amazon).

All Arawak languages distinguish singular and plural. Plural is only obligatory with human nouns. Plural markers are **-na/-ni* 'animate/human plural', **-pe* 'inanimate/animate non-human plural'. Dual

number is atypical. In Resígaro, markers of dual were borrowed from the neighboring Bora-Witoto languages.

Throughout the Arawak language family, nouns divide into those which must have a possessor (inalienably possessed) and those which do not have tohave a possessor (alienably possessed). Inalienably possessed nouns are body parts, kinship terms, and a few others, e.g., 'house' and 'name'. Inalienably possessed nouns have an 'unpossessed' form marked with a reflex of the suffix *-<*i* or *-*hV*, e.g., Pareci *no-tiho* 'my face', *tiho-ti* '(someone's) face'; Baniwa *nu-hwida* 'my head', *i-hwida-†i* (INDEFINITE-head-NON.POSSESSED) 'someone's head'. Alienably possessed nouns take one of the suffixes *-*ne/ni*, *-*te*, *-*re*, *-*i/-e* (Payne, 1991: 378), or *-*na* when possessed, e.g., Baniwa *nu-<inu-ni* (1sg-dog-possessive) 'my dog'.

The overwhelming majority of Arawak languages have a negative prefix *ma-* and its positive counterpart, prefix *ka-*, e.g., Piro *ka-yhi* (ATTRIBUTIVE-tooth) 'having teeth', *ma-yhi* (NEGATIVE-tooth) 'toothless'; Bare *ka-witi-w* (ATTRIBUTIVE-eye-FEMININE) 'a woman with good eyes', *ma-witi-w* 'a woman with bad eyes; a blind woman'.

The common Arawak lexicon (cf. Payne, 1991) consists mostly of nouns. There are quite a few body parts, fauna, flora, and artifacts. Only a few verbs can be reconstructed, e.g., **kau* 'arrive', **p^(da)* 'sweep', **po* 'give', **(i)ya* 'cry', **kama* 'be sick, die'; **itha* 'drink'. Most languages have just the numbers 'one' (proto-Arawak **pa-;* also meaning 'someone, another') and 'two' (proto-Arawak **(a)pi* and **yama*). A preliminary reconstruction is in Payne (1991). An up-to-date overview of the family is in Aikhenvald (1999a, 2001), and an overview of the proto-language is in Aikhenvald (2002).

Architecture of Grammar

R Kempson, King's College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A grammar of a language is by definition a formal model of the properties of language that are intrinsic to the words of the language and the way they can be combined. There are then a number of choices to make:

1. Should the explanation be defined solely to reflect structural properties of language, or should those properties in some sense be correlated with the way language is used in speaking or hearing?

This is the issue of language competence and its separation from language performance.

There is another criterion which a grammar might be required to meet, which might seem like just another way of putting the same question, but is taken as requiring a different answer:

2. Is it enough to provide a formal account of language structure, or should a grammar reflect general cognitive underpinnings, with the theory of grammar seen as part of a theory of mind?

This is the question of language as formal system vs. language as part of cognitive psychology.

There are then two debates about the internal design of the grammar to be considered. The first concerns the status of semantics in the grammar; the second concerns the status of the lexicon and its relation to syntax:

3. Should the grammar define a direct relation between the expressions of the language, and the entities in the world they are used to talk about; or should interpretation for natural-language expressions be defined in terms of concepts that the words express?

4. Is there some central body of properties that constitute the syntactic system of language, to be defined independently of the words that make up the language, or is the entire body of structural properties of language expressible as statements about words and their combinatorial properties?

These issues are not unrelated, as will emerge; but the following discussion takes these issues in turn, keeping them separate in so far as possible.

The Competence-Performance Divide

Even though interpretation of utterances invariably depends on the context in which that sentence is uttered, in seeking to explain natural language, linguists generally restrict their attention to those properties of language that are intrinsic to the words of the language and their mode of combination, defining grammars for individual languages to capture those aspects of sound-interpretation correlation that are not subject to variation context by context. This separation of linguistic analysis from any direct reflection of language as used in context led to what are called competence models of language (Chomsky, 1965, 1986, 1995). These define principles that determine the limits on sound-meaning correspondences both for any one language and for language in general; and they are articulated without consideration of any application in language use. Models of performance are then defined to articulate the mechanisms necessary to use such models in parsing and production (Fodor, 1981; Garrett, 2000; Gorrell, 1995; Levelt, 1989) and are taken to be dependent on the prior and independent articulation of such competence models. There is an immediate consequence to this separation. In virtue of the lack of direct correspondence between competence models and data culled from language performance, grammars can only be evaluated relative to a relatively abstract concept of data; and these data are judgements of wellformedness of sentence plus interpretation pairs as made by competent speakers of the language.

Grammars: Formal-Language Theory vs. Psychology

Reflecting such string-interpretation judgements, the architecture defined is modular, with more than one level of representation defined, in order to capture the distinct forms of generalization needed. Minimally, there are three kinds of generalization – phonological, syntactic and semantic – reflecting the existence of mappings from phonological form onto interpretation via some projection of intermediate structure, with the lexicon listing words with their phonological, syntactic, and semantic specifications. (Since not all languages are written, spoken language is taken to be primary.) The number and nature of such levels and the relation between them is, however, subject to debate. The debate is founded in two distinct points of departure for defining a grammar formalism, two different ways, that is, of answering question (2), which require two different ways of answering question (3).

The Formal-Language Pattern

On the one hand lies the formal-language tradition in which an articulated purpose-built formal system devised for the formal study of some (natural) phenomenon has a defined syntax, with an associated mapping from each licensed string onto some subset of the phenomenon under analysis. In such systems, the commitment to defining a concept of denotational content for the expressions of the language is definitional: the expressions pick out the objects under analysis, their denotation, for that is what the formal language is designed to do. The concept of compositionality is also true by definition: the meaning of a compound expression of the language is exclusively determined by the meaning of the parts and their mode of combination. Natural languages have been treated in like manner, explicitly following the formal language pattern (Montague, 1974). Categorial grammars, in particular, are faithful advocates of this formal-language tradition. They add to the characterization of a grammar some presumed specification of phonological properties of the listed primitive terms, but otherwise preserve the general architecture of a pairing of strings and denotational contents. with syntax no more than a systematic procedure for constructing pairings of phonological complexes and denotational contents for progressively larger units from words to sentences, with syntax

and semantics essentially in tandem (Moortgat, 1997; Morrill, 1994; Ranta, 1994; Steedman, 1996, 2000). As might be expected given the adherence to the formal-language pattern, comprehensive accounts of anaphora and attendant concepts of underspecification of denotational content are commonly not provided (though see Ranta, 1994 for a proof-theoretic reconstruction of context and anaphoric dependency), and advocates of categorial grammar formalisms generally do not evaluate their formalisms relative to criteria of psychological reality (though see Morrill, 2002 for exploration of using categorial-grammar constructs in the study of acceptability). Consequently, the categorial grammarian's answer to question (2) is to reject the need for cognitive underpinnings. And the answer to question (3) is that a direct mapping from natural-language expression to denotational content is central to natural-language grammar formalism.

The Language Faculty as a Subpart of Central Cognitive Systems

On the other hand, there is the psychology-based tradition, committed to the stronger form of answer to (2), and denying the formal-language stance on (3). Within the general cognitive-science perspective, processing of input stimuli by a cognitive system (seeing, hearing, smelling, etc.) involve special-purpose devices that enable internal representations to be constructed on the basis of which such input stimuli are assigned interpretation by the cognitive system, the human agent then using these internally constructed representations to reason to conclusions about what it is that he has seen/heard/smelled, etc. Minimally, on this view, modeling operations of the cognitive system involves defining a mapping from representations of those stimuli onto representations that are formulae of a deductive logical system (or systems), the internalized "language(s) of thought" (Fodor, 1983). The representation thus constructed as interpretation of the input stimulus may have to be assigned some denotational content underpinning the constructed interpretation depending on one's theory of mind, but it is the representation itself that constitutes the interpretation of the processed stimulus. There is a second property of such input systems, which natural language illustrates well. In all cases of input to the cognitive system, there is a gap between the information derived directly from some low-level representation of the input stimulus and the interpretation assumed by the cognitive system to be derived from it. This gap, which is essential to the flexibility and finite resources of the cognitive system itself, is filled by some mode of so-called non-demonstrative reasoning using other information as made available in the context. This perspective on natural-language modeling provides a very different starting point from the formal-language tradition, presuming as it does on a mapping from one form of representation to another, of which the input forms are systematically less rich than the output forms. In natural languages, this is displayed by pronouns and elliptical constructions, which provide an input to the interpretation process that is systematically less specified than how they are understood on any occasion of their use, having to be enriched by information that context makes available, in order to establish what information the anaphoric/elliptical expression conveys.

Chomskian grammars are the major representative of grammars adopting the psychological tradition of representationalism broadly construed, with all concepts of interpretation for natural language string articulated only as logical form representations (at the defined level of LF, see Chomsky, 1986, 1995 and elsewhere). On this view, syntax is defined as the core computational system with the levels of phonological form (PF) and logical form (LF) constituting interfaces with external systems (phonetic and intensional/conceptual systems, respectively). Central to this system is the characterization of discontinuities observable in all natural languages in which some expression may be indefinitely far from some position in the string with which, for interpretation purposes, it needs to be paired. These are cited by Chomsky as evidence that natural languages are not perfect formal systems (Chomsky, 1995), this departure justifying the irreducibility in the grammar architecture of the computational (syntactic) system. In capturing the supposed independence of the language computational system from the external systems with which it is interfaced, the minimalist system nevertheless respects general cognitive assumptions in so far as the internal properties of the language module have to be defined to allow interaction with general cognitive processes through these interface levels. As we would expect, given these assumptions, the properties of anaphora and ellipsis construal that are articulated as within the grammar formalism are expressed as syntactic principles.

Combining Formal Language and Psychological Traditions

Outside the Chomskian tradition, the three major grammar formalisms, Head-Driven Phrase-Structure Grammars (HPSG; Sag *et al.*, 2003), Tree-Adjoining Grammars (TAG; Joshi, 1987; Joshi and Kulick, 1995) and Lexical Functional Grammar (LFG; Bresnan, 2001; Dalrymple, 2001), all adopt a mixed approach, articulating semantics in terms of denotational

content, but nevertheless preserving some form of cognitivist perspective.

On the one hand, they reflect the formal-language tradition in assuming that a specification of denotational semantics for sentence strings is part of the grammar formalism. Even while respecting this assumption, they nevertheless depart from the restrictiveness of the syntax-semantics correspondence defined for formal languages. Building on the presumed independence of phonological generalizations from the remainder, they allow the independence of syntactic generalizations from the combinatorial system required for other levels. Grammar formalisms may be defined to allow an n-tuple of levels, each articulated with independent vocabulary and forms of generalization (see Dalrymple, 2001; Jackendoff, 2002), leading to the consequent challenge of articulating adequately restrictive correspondence rules between these independent levels (Dalrymple, 1999). Despite the relaxation of the tight architecture of formal-language grammar formalisms, the assumptions of compositionality, broadly construed, are preserved, with each word being assigned some n-tuple of phonological, syntactic, semantic, morpho-syntactic, information-structure, etc. each of which is in the form of constraints on its combinatorial potential, which then unify with specifications assigned to its neighboring items according as their specifications are consistent. Hence the term "unification-based grammars."

Notwithstanding their conforming broadly to formal-language assumptions, such grammars lay claim to assumptions of psychological reality not dissimilar to those laid out by Chomsky. In so far as they invoke a level of denotational semantics as part of the grammar formalism, however, they fail to be commensurate with the representationalist methodology. And some of them blur the competence/performance distinction in allowing a pragmatic component within the grammar formalism (Sag and Ginzburg, 2003), a problematic move, since pragmatics is the study of the general cognitive principles underpinning successful communication, hence not part of a natural-language grammar.

Issues of Grammar Design

The Status of the Lexicon

The different status of the lexicon in the overall system reflects the different importance assigned to the lexicon in the two traditions. Following the formal language tradition, categorial grammars, HPSG, and LFG are fully lexicalized, with the lexicon providing a list of input triples of phonological, syntactic and semantic specifications for each lexical entry, these constraint sets dictating the mode of combination of adjacent or otherwise co-occurring expressions in the phonological, syntactic and semantic domains, respectively. Earlier Chomskian paradigms assigned a smaller role to the lexicon, with syntactic principles determining the core computational actions that induce structure, hence in principle reflecting the psychological distinction between stored information to be retrieved from memory vs. on-line construction. Phonological and semantic interpretation processes were merely interpretive, interface, mechanisms applying to the two distinct types of output from the central syntactic device. The central status of syntax led to the Chomskian Principles and Parameters model of language being described as the T-model:

phonology ← syntax → logical form

Between the two extremes of full lexicalist and nonlexicalist approaches, TAG formalisms project, for each word (lexical item) entered in the lexicon, a family of local structures is defined as a stipulated form of input, but the nesting of these into larger structures is the result of general tree-adjoining mechanisms. In minimalist approaches, the lexicon plays a greater role than in earlier Chomskian models, but nevertheless detailed lexical specifications are not formally articulated.

The Syntax–Semantics Debate and the Grammar–Parser Relation

The discussion so far has presumed on the distinctness of syntax and semantics. Upon the formal-language stance, these are by definition distinct, for one is a representation, the other, being denotational, is purely interpretive of such representations. Given the representationalist methodology, however, the question arises whether representations defined as the syntactic mechanism for natural-language grammars constitutes anything more than a mechanism for progressively building the conceptual representations that constitute an interpretation of the signal. With a shift of perspective to one in which grammar formalisms are defined to model the mapping from phonological signals onto a progressively richer conceptual representation following the time-linear dynamics of on-line processing (Kempson *et al.*, 2001; Phillips, 2003; Cann *et al.*, 2005), exactly this simpler stance becomes available, with the bonus of a much more direct reflection of language in use. What have been thought of as irreducibly syntactic generalizations, in particular the discontinuity effects made famous in Chomsky's work as motivation for movement processes in syntax, become expressible as part of the progressive time-linear construction of the emergent conceptual

representation. On this view, the architecture of the grammar formalism acquires a directional dynamics, with phonological specifications providing input to actions that induce the building up of conceptual representations, as determined jointly by contextually provided structure, lexical specifications, and general structure-building processes:

phonology → syntax → logical form

The syntactic mechanism becomes simpler because instead of inducing a distinct syntactic structure and articulating a mapping between syntactic and phonological representations on the one hand and between syntactic and semantic (i.e., conceptual) representations on the other (as in the T-model), there is only the progressive construction of conceptual representations from phonological input. But such a shift leads to a radical narrowing of the traditional competence-performance dichotomy, for the competence model reflects the dynamics needed to model performance, and becomes directly embeddable into psycholinguistic models of the general cognitive system.

Summary

As these snapshots indicate, the architecture of the language faculty as defined in the various grammar formalisms reflect different claims about the status of language within an overall theory of mind. The significance of a parsing-directed design for natural-language grammars, introduced as a recent departure from orthodox assumptions, is that it leads to re-evaluation of the role of language in the theory of mind: any property of the architecture intrinsic to all natural language grammars is by assumption not merely a design feature of language itself, but a subpart of a general theory of cognitive psychology and a reflection of the human capacity for language use.

Areal Linguistics

L Campbell, University of Utah, Salt Lake City, UT, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction: Defining the Concept

Areal linguistics is concerned with the diffusion of structural features across language boundaries within a geographical area. The term 'linguistic area' refers to a geographical area in which, due to borrowing and language contact, languages of a region come to share certain structural features – not just loanwords, but also shared phonological, morphological, syntactic, and other traits. The terms 'sprachbund,' 'diffusion area,' 'adstratum relationship,' and 'convergence area' are also sometimes used to refer to linguistic areas. The central feature of a linguistic area is the existence of structural similarities shared among languages of a geographical area, where usually some of the languages are genetically unrelated or at least are not all close relatives. It is assumed that the reason the languages of the area share these traits is because they are borrowed.

There are two sorts of linguistic area studies. The more common circumstantialist approach lists similarities found in the languages of a geographical area, allowing the list of traits to suggest diffusion, but typically without seeking the historical linguistic evidence which could demonstrate that the traits are indeed diffused. Circumstantialist areal linguistics has been criticized, since it does not eliminate chance, universals, and possibly undetected genetic relationships as alternative possible explanations for shared traits. The historicist approach seeks concrete evidence showing that the shared traits are diffused. The historicist approach is preferred because it is more rigorous and reliable, although the lack of clear evidence in many cases makes reliance on the circumstantialist approach necessary in some situations (Campbell, 1985).

Linguistic areas are often defined, surprisingly, by a rather small number of shared linguistic traits.

Examples of Linguistic Areas

A good way to get a solid feel for linguistic areas and how they are defined is to look at some of the better-known ones. In what follows, some of the best-known linguistic areas are inspected briefly together with the more important of the generally accepted defining traits shared by the languages of each area.

The Balkans

The Balkans is the best known of all linguistic areas. The languages of the Balkans are Greek, Albanian, Serbo-Croatian, Bulgarian, Macedonian, and Romanian (to which some scholars also add Romani and Turkish). Some salient traits of the Balkans linguistic area are the following:

1. a central vowel /ɨ/ (or /ə/) (not present in Greek or Macedonian);
2. syncretism of dative and genitive cases (dative and genitive merged in form and function); this is illustrated by Romanian *fetei* 'to the girl' or 'girl's', as in *am data o carte* ***fetei*** 'I gave the letter **to the girl**' and *frate* ***fetei*** 'the **girl's** brother';
3. postposed articles (not in Greek), for example Bulgarian *mə^{j}ət* 'the man' / *mə^{j}* 'man';
4. periphrastic future (future signaled by an auxiliary verb corresponding to 'want' or 'have,' not in Bulgarian or Macedonian), as in Romanian *voi fuma* 'I will smoke' (literally 'I want smoke') and *am a cínta* 'I will sing' (literally 'I have sing');
5. periphrastic perfect (with an auxiliary verb corresponding to 'have');
6. absence of infinitives (rather with constructions such as 'I want that I go' for 'I want to go');
7. double marking of animate objects by use of a pronoun copy, as in Romanian *i-am scris lui Ion* 'I wrote to John', literally 'to.him-I wrote him John', and Greek *ton vlépo ton Jáni* 'I see John', literally 'him.ACC I see him.ACC John' (Sandfeld, 1930; Schaller, 1975; Joseph, 1992).

South Asia (the Indian Subcontinent)

The South Asia linguistic area is composed of languages belonging to the Indo-Aryan, Dravidian, Munda, and Tibeto-Burman language families. Some traits shared among different languages of the area are the following:

1. retroflex consonants, particularly retroflex stops;
2. absence of prefixes (except in Munda);
3. presence of a dative-subject construction (that is, dative-experiencer, as in Hindi *mujhe maaluum thaa* 'I knew it' ['to me' + 'know' + PAST]);
4. subject-object-verb (SOV) basic word order, including postpositions;
5. absence of a verb 'to have';
6. 'conjunctive or absolutive participles' – a tendency for subordinate clauses to have nonfinite verbs (that is, participles) and to be preposed; for example, relative clauses precede the nouns they modify;
7. morphological causatives;

8. so-called 'explicator compound verbs,' where a special auxiliary from a limited set is said to complete the sense of the immediately preceding main verb, and the two verbs together refer to a single event, as for example Hindi *le jaanaa* 'to take (away)' ('take' + 'go');
9. sound symbolic forms based on reduplication, often with *k* suffixed (for example in Kota, a Dravidian language: *kad-kadk* '[heart] beats fast with guilt or worry'; *a:nk-a:nk* 'to be very strong [of man, bullock], very beautiful [of woman]').

Some of these proposed areal features are not limited to the Indian subcontinent, but can be found also in neighboring languages (for example, SOV basic word order is found throughout much of Eurasia and northern Africa) and in languages in many other parts of the world. Some of the traits are not necessarily independent of one another; for example, languages with SOV basic word order tend also to have nonfinite (participial) subordinate clauses, especially relative clauses, and not to have prefixes (Emeneau, 1956; Masica, 1976; Emeneau, 1980; Emeneau, 2000).

Mesoamerica

The language families and isolates which make up the Mesoamerican linguistic area are Nahua (a branch of Uto-Aztecan), Totonacan, Otomanguean, Mixe-Zoquean, Mayan, Xinkan (Xinca), Tarascan (Purépecha), Cuitlatec, Tequistlatecan, and Huave. Five areal traits are shared by nearly all Mesoamerican languages, but not by neighboring languages beyond this area, and these are considered particularly diagnostic of the linguistic area:

1. nominal possession of the type *his-dog the man* 'the man's dog', as in Pipil (Uto-Aztecan) *i-pe:lu ne ta:kat*, literally 'his-dog the man';
2. relational nouns (locative expressions composed of noun roots and possessive pronominal affixes), of the form, for example, *my-head* for 'on me', as in Tzutujil (Mayan) *č-r-i:x* 'behind it, in back of it', composed of *č-* 'at, in', *r-* 'his/her/its' and *i:x* 'back', contrasted with *č-w-i:x* 'behind me', literally 'at-my-back';
3. vigesimal numeral systems, based on combinations of 20, such as that of Ch'ol (Mayan): *hun-k'al* '20' (1 × 20), *č-aʔ-k'al* '40' (2 × 20), *uʃ-k'al* '60' (3 × 20), *hoʔ-k'al* '100' (5 × 20), *hun-bahk'* '400' (1 × 400), *č-aʔ-bahk'* '800' (2 × 400), etc.;
4. nonverb-final basic word order (generally no SOV languages) – although Mesoamerica is surrounded by languages both to the north and south which have SOV (subject-object-verb) word order, languages within the linguistic area have VOS, VSO, or SVO basic order;
5. a number of loan translation compounds (calques) shared by the Mesoamerican languages, including examples such as 'boa' = 'deer-snake,' 'egg' = 'bird-stone/bone,' 'lime' = 'stone(-ash),' 'knee' = 'leg-head,' and 'wrist' = 'hand-neck'.

Since these five traits are shared almost unanimously throughout the languages of Mesoamerica but are found almost not at all in the languages just beyond the borders of Mesoamerica, they are considered strong evidence in support of the validity of Mesoamerica as a linguistic area. Four of these five traits have essentially the same distribution, clustering at the borders of Mesoamerica. Such bundling is uncommon in linguistic areas.

A large number of other features are shared among several Mesoamerican languages, but are not found in all the languages of the area, while some other traits shared among the Mesoamerican languages are found also in languages beyond the borders of the area (for details see Campbell *et al.*, 1986).

The Northwest Coast of North America

The Northwest Coast, the best known North American linguistic area, includes Tlingit, Eyak, the Athabaskan languages of the region, Haida, Tsimshian, Wakashan, Chimakuan, Salishan, Alsea, Coosan (Coos), Kalapuyan (Kalapuya), Takelma, and Lower Chinook (Chinook). These languages are characterized by elaborate systems of consonants, which include series of glottalized stops and affricates, labiovelars, multiple laterals, and uvular stops in contrast to velars. There are typically few labial consonants (labials are completely lacking in Tlingit and Tillamook and are quite limited in Eyak and most Athabaskan languages); in contrast, the uvular series is especially rich in most of these languages. There are typically few vowels, only three (*i, a, o*, or *i, a, u*) in several of the languages, four in others. Several of the languages have pharyngeals (*ʕ, ħ*), and most have glottalized resonants and continuants. Shared morphological traits include: extensive use of suffixes; near absence of prefixes; reduplication (of several sorts, signaling iteration, continuative, progressive, plural, collective, distribution, repetition, diminutive, etc.); numeral classifiers; alienable/inalienable oppositions in nouns; evidential markers in the verb, and verbal locative-directional markers; masculine/feminine gender (shown in demonstratives and articles); visibility/invisibility opposition in demonstratives. Aspect is more important than tense. All but Tlingit have passivelike constructions. The

negative appears as the first element in a clause regardless of the usual word order. Overt marking of nominal plurals, as in many American Indian languages, is absent or limited. Northwest Coast languages also have lexically paired singular and plural verb stems (that is, a lexical root may be required with a plural subject which is entirely different from the root used with a singular subject).

Some other traits are shared by a smaller number of Northwest Coast languages (see Campbell, 1997: 333–334; cf. Sherzer, 1976).

The Baltic

The Baltic linguistic area includes at its core (Balto-) Finnic languages (especially Estonian and Livonian), Baltic languages (Indo-European), and Baltic German; however, all of the following have been included in different treatments of the Baltic linguistic area: Old Prussian (Prussian) (extinct), Lithuanian, and Latvian (Baltic languages); the ten Saami (Lapp) languages, Finnish, Estonian, Livonian, Vote (Votian), Vepsian (Veps), Karelian, and others (of the Finnic branch of Finno-Ugric); High German, Low German (Low Saxon), Baltic German, and Yiddish (Western Yiddish) (West Germanic); Danish, Swedish, and Norwegian (North Germanic); Russian, Belorussian, Ukrainian, Polish, and Kashubian (Slavic); Romani (Indo-Aryan, branch of Indo-European); and Karaim (Turkic).

Shared features of the Baltic area include the following:

1. first-syllable stress;
2. palatalization of consonants;
3. tonal contrasts;
4. partitive case/partitive constructions (to signal partially affected objects, equivalent to, for example, "I ate [some] apple") in Finnic, Lithuanian, Latvian, Russian, Polish, etc.;
5. direct objects in the nominative case in a number of constructions which lack overt subjects (Finnic, Baltic, North Russian);
6. evidential mood: "John works hard (it is said/reported/inferred)" (Estonian, Livonian, Latvian, Lithuanian);
7. prepositional verbs (as German *aus-gehen* [out-to. go] 'to go out'): German, Livonian, Estonian, Baltic, and others;
8. subject-verb-object (SVO) basic word order;
9. agreement of adjectives in number with the nouns they modify (all languages of the area except Saami languages and Karaim); they also agree in case in all except the Scandinavian languages (which have lost case distinctions for adjectives); they also agree in gender in Baltic, Slavic, and Scandinavian languages, as well as in German, Yiddish, and some others.

For a more complete list of traits attributed to the Baltic linguistic area, see Zeps, 1962; Koptjevskaja-Tamm, 2002; and especially Koptjevskaja-Tamm and Wälchli, 2001; compare also Jakobson, 1931.

Ethiopia

Languages of the Ethiopian linguistic area include: Beja (Bedawi), Awngi, Afar, Sidamo, Somali, etc. (Cushitic languages); Geez, Tigré, Tigrinya (Tigrigna), Amharic, etc. (Ethiopian Semitic languages); Wellamo (Wolaytta), Kefa (Kaficho), Janjero (Yemsa), etc. (Omotic languages); Anyuak (Anuak) and Gumuz (Nilo-Saharan languages); and others. Among the traits they share are the following:

1. SOV basic word order, including postpositions;
2. subordinate clause preceding main clause;
3. gerund (nonfinite verb in subordinate clauses, often inflected for person and gender);
4. a 'quoting' construction (a direct quotation followed by some form of 'to say');
5. compound verbs (consisting of a nounlike 'preverb' and a semantically empty auxiliary verb);
6. negative copula;
7. plurals of nouns not used after numbers;
8. gender distinction in second- and third-person pronouns;
9. reduplicated intensives;
10. a different present tense marker for main and subordinate clauses;
11. a form equivalent to the feminine singular used for plural concord (feminine singular adjective, verb, or pronoun is used to agree with a plural noun);
12. a singulative construction (the simplest noun may be a collective or plural and it requires an affix to make a singular);
13. shared phonological traits such as *f* but no *p*, palatalization, glottalized consonants, gemination, presence of pharyngeal fricatives (*ħ* and *ʕ*) (Ferguson, 1976; Thomason, 2001; cf. Tosco, 2000).

How Linguistic Areas Are Defined

The following criteria have at times been considered relevant for attempts to establish linguistic areas: (1) the number of traits shared by languages in a geographical area, (2) bundling of the traits in some significant way (for example, clustering at roughly the same geographical boundaries), and (3) the weight or complexity of different areal traits (some

are accorded more significance for determining areal affiliation on the assumption that they are more difficult to acquire than others).

To establish a linguistic area, the more shared features the better. Linguistic areas in which many diffused traits are shared among the languages are considered better established. Nevertheless, some scholars believe that even one shared trait is enough to define a weak linguistic area (Campbell, 1985). In any event, it is clear that some areas are more securely established than others because they are supported by more shared areal traits. In the linguistic areas described above, the number and kind of shared traits vary considerably.

The idea that greater weight or importance should be attributed to some traits for defining linguistic areas can be illustrated with the borrowed word order patterns in the Ethiopian linguistic area. Ethiopian Semitic languages exhibit a number of interconnected word order patterns which are borrowed from neighboring Cushitic languages. Several of these traits reflect the diffusion of the SOV basic word order typology of Cushitic languages into the formerly VSO Ethiopian Semitic languages. Typologically the orders noun-postposition, verb-auxiliary, relative clause-head noun, and adjective-noun are all correlated and tend to co-occur with SOV order cross-linguistically. Their presence in Ethiopian Semitic languages (some with all of these, others with somewhat fewer) might seem to reflect several different diffused traits (SOV counted as one, noun-postposition as another, and so on), and might be taken as several independent pieces of evidence supporting the existence of the linguistic area. However, from the perspective of expected word order co-occurrences, these word order arrangements are not independent traits, but reflect the diffusion of a single complex feature, the overall SOV word order type with its tendency for the various expected coordinated orderings in typologically interrelated constructions to co-occur. However, if borrowed SOV word order is counted as a single diffused areal trait, it must rank high in significance for defining a linguistic area, since it is much more difficult for a language to change so much of its basic structure under areal influence than it is to acquire less complex traits.

Some scholars had thought that the bundling of areal traits, clustering at the boundaries of a linguistic area, might be required for defining linguistic areas, though this has proven a poor criterion. Linguistic areas are similar to traditional dialects, where often one trait spreads across more territory than another trait, so that their boundaries (or territories) do not coincide (do not 'bundle'). Typically the geographical extent of individual traits may vary considerably. However, in the rare situation where the traits do coincide at a clear boundary, the definition of a linguistic area matching their boundary is relatively secure. As mentioned, several of the traits in the Mesoamerican linguistic area do have the same boundary, but typically in other areas the areal traits do not share the same geographical boundaries, offering no clearly identifiable outer border of the linguistic areas in question.

Implications of Areal Linguistics for Linguistic Reconstruction and Subgrouping

Areal diffusion can have important implications for comparative reconstruction and for subgrouping within known language families. Nootkan provides a good example which illustrates this. The sound correspondences upon which Nootkan subgrouping is based are given in Table 1.

Nitinat and Makah appear to share the innovation which changed nasals to corresponding voiced stops (in [1]–[4]), while Nitinat and Nootka appear to share the change of the glottalized uvulars to pharyngeals (in [5] and [6]). (Makah and Nitinat also share the retention of uvular fricatives, which Nootka has changed to a pharyngeal [in (7) and (8)]; however, shared retentions are not valid evidence for subgrouping.) Here, one innovation (denasalization) suggests a subgrouping of Makah and Nitinat together, with Nootka more distantly related, while the other innovation (pharyngealization) suggests Nitinat and Nootka together, with Makah less closely related. This seeming impasse is solved when we take into account the fact that the absence of nasals is an areal feature shared by several other languages of the area; it diffused into both Makah and Nitinat under areal influence and is thus not real evidence of a shared common development before the languages separated; rather, it reached these two languages independently from elsewhere in the linguistic area. The innovation shared by Nitinat and Nootka of

Table 1 Nootkan sound correspondences

	Makah	*Nitinat*	*Nootka*	*Proto-Nootkan*
1.	b	b	m	*m
2.	b'	b'	m'	*m'
3.	d	d	n	*n
4.	d'	d'	n'	*n'
5.	q'	ʕ	ʕ	*q'
6.	q'^{w}	ʕ	ʕ	*q'^{w}
7.	χ^{w}	χ^{w}	ħ	*χ^{w}
8.	χ	χ	ħ	*χ

(Haas, 1969).

glottalized uvulars changing to pharyngeals (in [5] and [6]) is real evidence of subgrouping – a true (nondiffused) shared innovation. So, Nitinat and Nootka together constitute one branch of the family, Makah the other branch. Moreover, with respect to areal implications for reconstruction, if we did not know about the areal diffusion in this case, we might be tempted to reconstruct the voiced stops in Proto-Nootkan, since they occur in more languages than the nasals do, and to postulate a change of these to nasals in Nootka (for [1]–[4]), getting it wrong in this case. Thus, areal linguistic traits can have important implications for classification (subgrouping) and for reconstruction.

Areal Linguistics and Proposals of Distant Genetic Relationship

Some similarities among languages which are due to areal diffusion are often mistakenly taken to be evidence of a possible distant family relationship among languages whose classification is in question. The Mosan hypothesis, which proposes a genetic relationship between the Salishan, Wakashan, and Chimakuan language families, illustrates this problem, which is common in many instances of long-range comparison. Several scholars noted structural similarities among these Northwest Coast languages, but the Mosan hypothesis was not found convincing because much of the evidence turned out to rely on areal traits widely borrowed in the Northwest Coast linguistic area. Swadesh (1953) presented 16 shared structural similarities in support of Mosan, but most of these are Northwest Coast areal features (some of the traits are also typologically commonplace, found independently in languages throughout the world), for example:

1. "Extensive use of suffixes."
2. "Nearly complete absence of functioning prefixes in Chimakuan and Wakashan, minor role in comparison to the suffixes in Salish." (Typologically it is not unusual for suffixing languages to lack prefixes.)
3. "Extensive use of stem reduplication, including initial reduplication . . . and . . . full stem reduplication."
4. "Aspect, including at least the dichotomy of momentaneous and durative."
5. "Tense is an optional category."
6. "Plural is an optional category."
7. "Dichotomy of non-feminine versus feminine gender shown in demonstratives and articles."
8. "Numeral classifier notions, shown by suffixes."
9. "Two alternate stems for number" (lexically paired distinct singular and plural verb stems).
10. "Lexical suffixes . . . referring to body parts and other space references."
11. "Predicative use of nouns."
12. "Demonstrative distinctions such as the present versus absent, or visible versus invisible."

As is clear, the traits which Swadesh listed as evidence for the Mosan hypothesis are better explained as the results of diffusion within the Northwest Coast linguistic area (see Campbell, 1997 for details.)

From this case, it is easy to see why the identification of areal traits is so important in historical linguistics. In this instance, failure to recognize the areal borrowings led to an erroneous proposal of genetic relationship among neighboring language families.

Kinds of 'Linguistic Area'

It is generally recognized that things that have been called linguistic areas include entities with widely divergent character and historical backgrounds, depending on the social, cultural, political, geographical, attitudinal, and other factors which correlate with diffusion of linguistic features in different regions (Dahl, 2001: 1458; Kuteva, 1998: 308–309). As Thomason (2001: 104) explained,

> [linguistic areas] arise in any of several ways – through social networks established by such interactions as trade and exogamy, through the shift by indigenous peoples in a region to the language(s) of invaders, through repeated instances of movement by small groups to different places within the area.

One finds in the literature many different sorts of linguistic areas, such as: incipient ones, only beginning to form and with as yet few shared traits; moribund and decaying ones, where, due to many changes after the area was actively formed, fewer traits are currently recognizable among the languages; overlapping ones, where different areas formed on top of or partially overlapping one another at different times for different reasons; multilateral (areal traits spreading from various languages of the region) versus unilateral areas (with the traits shared throughout the languages of an area stemming predominantly from one language); areas due to rapid conquest, population spread, and migration (traits moving with movement of speakers), others through home-grown, stay-in-place contact (movement of traits but not of peoples); and disrupted areas with "latecomers, earlier drop-outs, and temporary passers-by" (Stolz, 2002: 265). "In short, the notion 'linguistic area' does not refer to a uniform phenomenon, either socially or linguistically" (Thomason, 2001: 115). This array of different kinds of linguistic area raises questions about whether the notion of 'linguistic

area' is warranted, whether all these different 'objects' legitimately qualify as 'linguistic areas,' given their very different natures and composition and given the very different circumstances of their birth (and decay). The notion of 'linguistic area' offers little upon which these different sorts of linguistic areas can be united other than the fact that they all involve borrowing in some way, but borrowings of different sorts, for different reasons, in different settings, and at different times.

Linguistic Areas versus Borrowing Generally

It is generally acknowledged that linguistic areas are "notoriously messy," "notoriously fuzzy" things (Thomason and Kaufman, 1988: 95; Heine and Kuteva, 2001: 396; Tosco, 2000: 332), and that "what we understand about linguistic areas is depressingly meager" (Thomason, 2001: 99). A common perception is that the term 'linguistic area' is difficult to define (cf. Heine and Kuteva, 2001: 409). As Thomason (2001: 99) observed, "linguistics has struggled to define the concept ever since [Trubetzkoy, 1928], mainly because it isn't always easy to decide whether a particular region constitutes a linguistic area or not." Stolz (2002: 259) believed that "the search for clearcut definitions [of 'Sprachbund, linguistics area, and areal type'] has been largely futile and will probably never come to a really satisfying conclusion." In spite of prolonged efforts to define 'linguistic area,' there is no general agreement on its definition, and even for the most widely accepted linguistic areas, such as the Balkans, scholars do not agree wholly on which languages belong to the area, what linguistic traits characterize the area, and what its precise geographical extent is. This difficulty has been related to the lack of clear distinction between areal phenomena and borrowing generally (Campbell, in press). Thus Dahl (2001: 1458) asked:

> In the end, we are led to the following more far-going question about the notion of area: to what extent do areas . . . have a reality of their own and to what extent are they just convenient ways of summarizing certain phenomena? At the most basic level, linguistic contact relationships are binary: one language influences another. An area is then simply the sum of many such binary relationships.

Campbell (in press) argues that the various definitions of 'linguistic area' offered in the literature confirm that linguistic areas amount to just the study of local linguistic borrowing and its history. Every 'linguistic area,' to the extent that the notion has any meaning at all, arises from an accumulation of individual cases of 'localized diffusion'; it is the investigation of these specific instances of diffusion, and not the pursuit of defining properties for linguistic areas, that increases our understanding and explains the historical facts. With the focus rather on specific instances of borrowing, many of the unresolved issues and indeterminacies which have dogged areal linguistics from the outset cease to be relevant questions. It is the diffused linguistic changes themselves that count and not the attempt to seek meaning in the geography that secondarily is involved (Campbell, 2004). A linguistic area, to the extent that it many have a legitimate existence at all, is merely the sum of borrowings in individual languages in contact situations. If we focus rather on understanding borrowings, those contingent historical events, the difficulty of determining what qualifies as a legitimate linguistic area ceases to be a problem.

Argentina: Language Situation

P Gonzalez, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Argentina is the largest Spanish-speaking country in South America. Its natural borders are the Atlantic on the east side and the Andes on the west side, which separate Argentina and Chile. Argentina also shares borders with Bolivia and Paraguay on the north, and with Uruguay and Brazil on the east. There are 40 million Argentineans; 12 million live in the capital, Buenos Aires.

Spanish is the official language in Argentina. Spanish colonializers arrived in 1516 and Argentina remained a colony until 1816, when it officially obtained its independence. The Spanish spoken in Argentina is remarkable in several ways, as several factors have influenced its dialectal differentiation. One factor is its contact with indigenous languages, which have had the greatest influence on the lexicon. Quechua in the northwest, Guaraní in the northeast, and Mapudungun in the south are languages that have contributed with numerous words to the everyday lexicon, above all regional, and in some cases they have left traces in pronunciation and morphosyntactic phenomena. Quechua is an indigenous language of the Andean region, spoken by approximately 13 million people in Argentina, Bolivia, Chile, Colombia, Ecuador, and Peru. It was the official language of the Inca Empire. Guaraní belongs to the Tupi-Guaraní language subfamily. There are approximately six million Guaraní speakers worldwide. Mapudungun is an Araucanian language spoken in Chile and Argentina by the Mapuche people. It is also known as Araucano and Mapuche. It has about 440 000 speakers, with about 40 000 in Argentina. The influence of these native languages explains part of the regional distinction of the Spanish in the Argentinean territory.

European languages have also had a great influence on the Spanish dialect of Argentina, especially Italian. This influence is due to the high number of European migrants that arrived in Argentina from the second half of the 19th century until the end of the 20th century. Apart from Italians, other nationalities were

Argentina: Language Situation

P Gonzalez, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Argentina is the largest Spanish-speaking country in South America. Its natural borders are the Atlantic on the east side and the Andes on the west side, which separate Argentina and Chile. Argentina also shares borders with Bolivia and Paraguay on the north, and with Uruguay and Brazil on the east. There are 40 million Argentineans; 12 million live in the capital, Buenos Aires.

Spanish is the official language in Argentina. Spanish colonializers arrived in 1516 and Argentina remained a colony until 1816, when it officially obtained its independence. The Spanish spoken in Argentina is remarkable in several ways, as several factors have influenced its dialectal differentiation. One factor is its contact with indigenous languages, which have had the greatest influence on the lexicon. Quechua in the northwest, Guaraní in the northeast, and Mapudungun in the south are languages that have contributed with numerous words to the everyday lexicon, above all regional, and in some cases they have left traces in pronunciation and morphosyntactic phenomena. Quechua is an indigenous language of the Andean region, spoken by approximately 13 million people in Argentina, Bolivia, Chile, Colombia, Ecuador, and Peru. It was the official language of the Inca Empire. Guaraní belongs to the Tupi-Guaraní language subfamily. There are approximately six million Guaraní speakers worldwide. Mapudungun is an Araucanian language spoken in Chile and Argentina by the Mapuche people. It is also known as Araucano and Mapuche. It has about 440 000 speakers, with about 40 000 in Argentina. The influence of these native languages explains part of the regional distinction of the Spanish in the Argentinean territory.

European languages have also had a great influence on the Spanish dialect of Argentina, especially Italian. This influence is due to the high number of European migrants that arrived in Argentina from the second half of the 19th century until the end of the 20th century. Apart from Italians, other nationalities were

also present in the Argentina of the beginning of the 20th century: Polish, Russian, French, and German.

Apart from the characteristics the Argentinean variety of Spanish shares with the rest of Latin America, Argentina has its own typical features. The most characteristic trait of this variety is the *voseo*: the use of the pronoun *vos* and its own verbal form for the second person singular of the present tense, instead of *tú*. This appears in the indicative and imperative modes. In the lexicon, there are more Anglicisms in the Spanish spoken in Argentina than in the rest of the Spanish-speaking world, for example, *barman, box, film, sandwich*.

The immigration of thousands of Italians to Buenos Aires and other large cities of the Río de la Plata in the first decades of the 20th century gave rise to a significant demographic change. The percentage of Italians in the overall population increased from 25% to more than 50%. Italians had the advantage of being understood by only minimally modifying their Italian speech. These modifications became a new way of talking: the Cocoliche. Cocoliche is the mixed Italic-Spanish speech used by the first generation of Italian immigrants; it was associated with the lowest social classes. Cocoliche was perceived as being laughable and funny, and almost immediately became a literary stereotype that appeared in comics, journalistic essays, novels, poems, and theatre plays. As soon as immigration decreased and the descendants of the first born immigrants had acquired Spanish as their first language, the Cocoliche started to disappear, and today it is remembered more as a creation of popular culture than as a form of speech that was used in the past by a large percentage of the population of Buenos Aires.

Argument Structure

A Alsina, Universitat Pompeu Fabra, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Concept and Motivation

In order to predict the syntactic behavior of a predicate, such as a verb, we need to know at least:

1. how many syntactic dependents it takes,
2. what type of syntactic dependents it takes, for example, whether it takes a subject and an object, or a subject and a prepositional complement, etc.,
3. which of its semantic roles (or thematic roles) corresponds to each of its dependents.

Argument structure is the grammatical representation of a predicate needed to derive this information in all of the uses of the predicate, for example, in both its active and passive form, in both its verbal and nominal form, etc. The notion of argument structure can be thought of as replacing the concept of syntactic subcategorization.

The motivation for positing argument structure as a distinct level of representation is provided by various observations:

1. The observation that semantically similar verbs tend to pattern alike in terms of the syntactic dependents that they take suggests that there is a regularity in the correspondence between semantic structure and syntactic structure. It has often been noted that a predicate involving an agent and a patient normally has the agent expressed as the subject and the patient as an object, and never the other way around in languages like English. If we just stipulated the correspondence between semantic roles and grammatical functions for every predicate in the language, we would be missing important generalizations. We would also be unable to predict the behavior of newly coined words. For example, if we invented the verb *obliquate* meaning "to build or place in an oblique orientation," there would only be one way in which the arguments of this verb could be expressed: the causer or agent role would be expressed as the subject and the theme as the object, as in (1a), and the reverse assignment of semantic roles to grammatical functions, shown in (1b), would be impossible (Alsina, 1996a: 6).

Argument Structure

A Alsina, Universitat Pompeu Fabra, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Concept and Motivation

In order to predict the syntactic behavior of a predicate, such as a verb, we need to know at least:

1. how many syntactic dependents it takes,
2. what type of syntactic dependents it takes, for example, whether it takes a subject and an object, or a subject and a prepositional complement, etc.,
3. which of its semantic roles (or thematic roles) corresponds to each of its dependents.

Argument structure is the grammatical representation of a predicate needed to derive this information in all of the uses of the predicate, for example, in both its active and passive form, in both its verbal and nominal form, etc. The notion of argument structure can be thought of as replacing the concept of syntactic subcategorization.

The motivation for positing argument structure as a distinct level of representation is provided by various observations:

1. The observation that semantically similar verbs tend to pattern alike in terms of the syntactic dependents that they take suggests that there is a regularity in the correspondence between semantic structure and syntactic structure. It has often been noted that a predicate involving an agent and a patient normally has the agent expressed as the subject and the patient as an object, and never the other way around in languages like English. If we just stipulated the correspondence between semantic roles and grammatical functions for every predicate in the language, we would be missing important generalizations. We would also be unable to predict the behavior of newly coined words. For example, if we invented the verb *obliquate* meaning "to build or place in an oblique orientation," there would only be one way in which the arguments of this verb could be expressed: the causer or agent role would be expressed as the subject and the theme as the object, as in (1a), and the reverse assignment of semantic roles to grammatical functions, shown in (1b), would be impossible (Alsina, 1996a: 6).

(1) a. Jim obliquated the door of the closet.
b. *The door of the closet obliquated Jim.

This shows that the correspondence between semantic roles and grammatical functions is governed by principles that are active even with newly formed words. Furthermore, this correspondence does not seem to vary depending on all possible semantic differences among semantic roles, since verbs that have quite different semantic roles behave alike as far as this correspondence is concerned. For example, verbs such as *see* and *love*, which are usually said to take an experiencer role and a stimulus (or theme) role, pattern like causative verbs such as *cut* or *lift*, which take a causer and a patient, in that the experiencer role behaves like the causer role in being selected as the subject, whereas the other role is mapped onto the object. This suggests the need for an intermediate level of representation between the level that represents semantic information such as the semantic roles of predicates and the level that represents grammatical functions: this intermediate level – argument structure – distills semantic information into those distinctions that are relevant for assigning grammatical functions to arguments, as well as for other grammatical properties.

2. The fact that a given verb, with a fixed set of semantic roles, can appear with a different set of grammatical functions in different syntactic structures, depending on the morphology on the verb or other factors, suggests that there is an abstract representation of the grammatical dependents of the verb that is common to the various syntactic frames in which it appears. This gives rise to an alternation in the correspondence between semantic roles and grammatical functions. A clear example of this alternation occurs in causative structures, compared with their noncausative counterparts. In the Bantu language Chichewa, the agent role of the simple, noncausative verb *–lemb-a* is expressed as the subject, as in (2a); however, when this verb root combines with the causative morpheme, that semantic role is expressed as the object, as in (2b) (Alsina, 1997: 209).

(2) a. Mkângo u-ku-lémb-á ndakatūlo.
3.lion *3.SUBJ-PRES-write-INDIC* *9.poem*
'The lion is writing a poem.'

b. Mlīmi a-ku-lémb-éts-a
1.farmer *1.SUBJ-PRES-write-INDIC*
mkángó ndakatūlo.
3.lion *9.poem*
'The farmer is making the lion write the poem.'

If we assume that there is a fixed representation for the arguments of a verb root such as *-lemb-a*, we cannot assume that this representation is encoded in terms of grammatical functions or phrase structure positions, because these are different depending on whether the verb root combines with the causative morpheme or not.

3. The observation that certain properties of arguments are not reducible to grammatical functions, to constituent structure, or to semantic structure suggests that there is a different level of organization of arguments that is relevant to those properties. Some languages have reflexives that can be bound either by a grammatical subject or by the logical subject of a passive clause. This is the case in Hindi with the reflexive *apnaa*, as illustrated in (3) (Mohanan, 1994: 123): whereas the active clause (3a) has only one possible antecedent of the reflexive, the corresponding passive clause (3b) has two.

(3) a. vijay-ne ravii-ko apnii
Vijay-ERG *Ravi-ACC* *self-GEN*
saikil-par biʈʰaayaa.
bicycle-LOC *sit-CAUS-PERF*
'Vijay$_j$ seated Ravi$_i$ on self's$_{j/*i}$ bike.'

b. ravii vijay-se apnii saikil-par
Ravi-NOM *Vijay-INSTR* *self-GEN* *bicycle-LOC*
biʈʰaayaa gayaa
sit-CAUS-PERF *go-PERF*
'Ravi$_i$ was seated by Vijay$_j$ on self's$_{i/j}$ bike.'

A similar argument has been made on the basis of binding in ergative languages by Manning, 1996, Wechsler, 1999, and Wechsler and Arka, 1998. In these languages, the logical subject, or most prominent argument on argument structure, can bind a reflexive that is a less prominent argument, even though the latter may be the grammatical subject and the former may be a nonsubject of the same clause.

All of these facts point to the existence of a level of organization of the arguments of a predicate – argument structure – that interfaces between semantic structure and syntactic information about grammatical functions, case, binding, and other properties.

Argument structure is a theoretical construct and, as such, it varies in its content, formal representation, and function in the grammar depending on the larger theory of grammar of which it is part, as well as on many theoretical choices made by each author. One, therefore, cannot hope to give a theory-neutral presentation of argument structure. One can point to the main areas of divergence in theories of argument structure and to the ideas on which there is widespread consensus. In what follows, I will point to some differences in the treatment of argument structure, will present arguments that favor specific views about argument structure, and will provide an account of certain facts that relies on argument structure and a theory of the mapping between argument structure and morphosyntactic expressions.

Different Conceptions of Argument Structure

An important line of research in linguistics is the enterprise of deriving as much syntactic information about the patterning and distribution of verbs and their dependents as possible from the meanings of these verbs. The idea of argument structure is part of this enterprise, where it plays an intermediate role in the mapping from semantic information to morphosyntactic realization. Given this role, there is some division as to whether argument structure is a semantic level of representation or a syntactic one and as to how much semantic and syntactic information should be part of argument structure.

Argument Structure as a Semantic Representation

One of the clearest proponents of argument structure as a semantic level of representation is Jackendoff (1990). This work develops a representation for semantic structure, or Lexical Conceptual Structure (LCS), which represents the arguments of a predicate as positions in conceptual structure. LCS expresses distinctions among thematic roles, captures selectional restrictions, etc. It also provides a representation for argument structure as the set of constituents at LCS marked as arguments (Jackendoff, 1990: 252). Given the claim in Jackendoff (1990) that a single NP can be coindexed with more than one position at conceptual structure (i.e., have multiple theta-roles) and that a position at conceptual structure may not correspond to any syntactic expression (implicit argument), it sometimes has to be stipulated whether a position at conceptual structure has argument status or not. In addition, Jackendoff (1990) provides a set of linking rules for predicting the syntactic status of the arguments in an LCS.

Butt (1995) proposes a theory of argument structure based on Jackendoff's (1990) approach and assumes that semantic information should be represented at the argument structure level and not at a separate level (Butt, 1995: 136). In Butt's argument structure, there is a representation of the thematic tier, expressing distinctions such as actor, goal, or theme, a representation of the action tier, providing contrasts between agent and patient, and a representation of the aspectual tier, indicating whether the beginning, middle, and end of an event are lexically specified. These distinctions are relevant for explaining restrictions in complex predicate formation. Another approach that takes argument structure to be a semantic level is Pustejovsky (1995).

Argument Structure as a Phrase Structure Representation

Among the proponents of argument structure as a syntactic representation, there are some who take it to be a structure of the same type as that used for representing syntactic constituents and categories, namely, a phrase structure. In the theoretical framework of Principles and Parameters and the Minimalist Program, all syntactic information tends to be represented by means of phrase structure, including information about grammatical functions. Within this framework, it is natural to attempt to view argument structure also as a phrase structure, which is the approach taken by Hale and Keyser (1993, 1997, 2002). Not only do these authors view argument structure as syntax and as a syntactic structure of the same formal type as that used to represent grammatical functions and grammatical categories, but they assume it conforms to principles of syntax required independently of argument structure. They claim that "there are no linguistic mechanisms that are specific to argument structure" (Hale and Keyser, 1993: 93).

Among other phenomena, they attempt to explain contrasts such as the presence of the causative alternation with verbs such as *get* and its absence with verbs such as *put*. They propose to derive denominal verbs such as *corral* and *saddle* through incorporation of the homonymous noun from the complement of a preposition into this preposition and into the governing verb. According to the authors, the proposal to derive denominal verbs through head movement explains the range of meanings that these verbs have, such as the fact that the incorporated noun never corresponds to the agent or causer role, since that would not be allowed by the principles regulating syntactic movement (Hale and Keyser, 1993: 60). Despite the attractiveness of this approach, particularly for researchers in the framework of Principles and Parameters or Minimalist Program, Kiparsky (1997a) presents serious objections to the attempt to reduce argument structure to phrase structure categories and principles and argues that the syntactic behavior of verbs, such as whether they undergo the causative alternation or not, is best explained by appealing to semantic properties.

Argument Structure as an Autonomous Syntactic Representation

A prevalent approach to argument structure within various different theoretical frameworks is the assumption that argument structure is a syntactic level of representation that is different from the

representation of grammatical categories and grammatical functions not only in the substance that it expresses, but also in the formal design used for it. This is the position, among others, of Grimshaw (1990) and Levin and Rappaport (1995), within the framework of GB or Principles and Parameters; of Alsina (1992, 1996a, 1996b, 2001a, 2001b, 2003), Alsina and Mchombo (1993), Bresnan (2001), Bresnan and Kanerva (1989), Bresnan and Moshi (1990), Manning (1996), Mohanan (1994), within the framework of LFG; of Davis (2001), Manning and Sag (1998), Wechsler (1995, 1999), Wechsler and Arka (1998), within the framework of HPSG; of Goldberg (1995), within the framework of Construction Grammar; and of Ackerman and Moore (2001), Kiparksy (1997b, 2001), and Wunderlich (1997), within frameworks akin to the last three cited.

All of these theories of argument structure have certain ideas in common: argument structure is a list of arguments (or argument positions); these arguments are ranked by prominence; this ranking is constrained by the semantic properties of the arguments involved; the arguments are mapped (or linked) to morphosyntactic expressions by means of general correspondence principles. The hierarchical ranking of arguments, common to all of these theories, allows for the definition of the notion of logical subject, also referred to as argument structure subject or a-subject. This notion plays a prominent role in accounting for binding and control phenomena, as well as for linking, since the logical subject, as a default, maps onto the grammatical subject. Example (3) provides an illustration of the relevance of this notion to the binding of a reflexive in Hindi. According to Joshi (1993), the anaphor *apaṇ* in Marathi can only be bound by a logical subject, regardless of its grammatical function. In control structures in Tagalog, Kroeger (1993: 39, 99) shows that the control target or controlee must be a logical subject, whether it is a grammatical subject or not.

In some of these theories, no information is present on argument structure beyond the hierarchical ranking of arguments, whereas, in others, more information is specified. The notion of an external argument (the canonical subject of active transitive verbs and of unergative verbs such as *work*) is an added distinction among arguments that plays an important role in some theories, such as Grimshaw (1990). Theories that represent this notion at the level of argument structure represent the distinction between the two classes of intransitive verbs – unergative and unaccusative verbs – at this level, as those that have an external argument and those that do not, respectively.

Another element of divergence among these theories is whether the argument positions at the argument structure level are represented as the same type of formal object as the morphosyntactic expressions that realize those arguments or as a different type of formal object. Recent work within HPSG assumes that the argument structure is a list of syntactic categories, such as NP, PP, VP, etc., which are structure-shared with the appropriate elements filling the various grammatical functions that the predicate subcategorizes for. Other work does not assume structure-sharing between the elements at the level of argument structure and at the level of grammatical functions, but simply a correspondence or linking between them, which allows for the possibility of having different information at the different levels.

There is a split among the theories mentioned as to whether thematic role labels should be represented at the level of argument structure or not, given that some authors include labels such as agent, locative, and patient in the argument structure and others do not. However, this is more of an apparent split, since there is a general consensus that semantic information, such as thematic roles or semantic entailments about arguments, should be represented at a semantic level of representation, such as lexical conceptual structure. It would, therefore, be redundant to include this type of information at two different levels of representation. Those authors who use thematic role labels in the argument structure do so more for convenience (for identifying the arguments involved), than for a theoretical position.

Argument Structure: A Syntactic Structure with Unique Information

In what follows, I will present an argument for the claim that argument structure (a) contains syntactic information, as opposed to semantic information, and (b) that the arguments on argument structure are classified in a way that is unique to argument structure. This allows us to conclude that argument structure is not a semantic level of representation, but a syntactic one whose features are unique to this level.

The Distinction Between Primary and Secondary Objects

In certain languages, internal arguments in double object constructions show an asymmetrical behavior. I will illustrate this for the Bantu language Chichewa, where, in a given structure, at most one of the two internal arguments may have one of the following properties, which we can call primary object properties:

- be encoded as an object marker (a pronominal object affix);
- be promoted to subject in a passive clause;
- be bound to the logical subject in the reciprocal construction;
- the internal argument that can display these properties is constrained to precede the other object when both are NP objects following the verb.

In a construction where one of the internal arguments is thematically a beneficiary and the other one a patient, the beneficiary argument, as an object NP, is constrained to precede the patient object, as in (4a); the beneficiary argument must be the subject in the corresponding passive clause, as in (4b); in the reciprocal construction, the beneficiary must be bound to the logical subject so that there is a single NP corresponding to both bound roles, as in (4c) (from Alsina, 2001a: 81–91).

(4) a. Nkhāndwe zi-ku-mény-ér-a
10.foxes *10.SUBJ-PRES-hit-APPL-INDIC*
aná njōvu.
2.children *9.elephant*
'The foxes are hitting the elephant for the children.'
*'The foxes are hitting the children for the elephant.'

b. Ăna a-ku-mény-ér-edw-á
2.children *2.SUBJ-PRES-hit-APPL-PASS-INDIC*
njōvu (ndí nkhāndwe).
9.elephant *by 10.foxes*
'The elephant is being hit for the children (by the foxes).'
*'The children are being hit for the elephant (by the foxes).'

c. Nkhāndwe zi-ku-mény-ér-an-a njōvu.
10.foxes *10.SUBJ-PRES-hit-APPL-RECIP-INDIC* *9.elephant*
'The foxes are hitting the elephant for each other.'
*'The foxes are hitting each other for the elephant.'

The same contrast is revealed with respect to the ability to be encoded by means of an object marker: only the beneficiary object has this ability, as shown in Alsina (2001a, 2003), Alsina and Mchombo (1993), and Bresnan and Moshi (1990), among others. Thus, we see that a theme or patient object in a construction with a beneficiary internal argument is blocked from displaying any of the primary object properties: it cannot precede the other object, cannot be the passive subject, cannot be the target of reciprocalization, and cannot be encoded by means of an object marker. This is in contrast to what occurs in a structure where the theme or patient argument is the sole internal argument of the construction: it can be the passive subject, can be the target of reciprocalization, and can be expressed by means of an object marker. These properties are illustrated in (5), for the active/passive pair based on the verb stem *-meny-a* (Alsina, 2001a: 93):

(5) a. Nkhāndwe zi-ku-mény-á njōvu.
10.foxes *10.SUBJ-PRES-hit-INDIC* *9.elephant*
'The foxes are hitting the elephant.'

b. Njovu i-ku-mény-ëdw-a
9.elephant *9.SUBJ-PRES-hit-PASS-INDIC*
(ndí nkhāndwe).
by 10.foxes
'The elephant is being hit (by the foxes).'

The contrast between the ability of the patient argument to display primary object properties when it is the sole internal argument of the construction, as in (5), and the inability of the same argument to do so when it co-occurs with a beneficiary internal argument, as in (4), cannot be attributed to a semantic contrast for several reasons. In the first place, there is no difference in the semantic role of the patient internal argument of (5) and of (4). In the second place, in constructions in Chichewa where the patient or theme argument co-occurs with a goal argument that can be alternatively an oblique or an object (as with *-perek-a* 'hand' and its applicative form *-perek-er-a*, respectively), without any semantic difference correlating with the syntactic difference, the theme or patient argument can display primary object properties only when the co-occurring goal is an oblique, i.e., not an internal argument. In the third place, other languages, called symmetrical by Bresnan and Moshi (1990), allow both internal arguments in structures semantically equivalent to (4) to display primary object properties either alternatively or simultaneously. Since the presence or absence of the ability to display such properties cannot plausibly be explained by appealing to semantic contrasts, it has to be explained by positing a syntactic feature to distinguish an argument that can display these properties from an argument that cannot do so.

Bresnan and Moshi (1990) proposed to represent the contrast between these two types of argument at the level of argument structure (as well as at the level of grammatical functions), and Alsina (2001b) presented arguments for this position and for assuming that the distinction between the two types of internal argument is represented only in argument structure. The argument in Alsina (2001b) for representing the distinction between the two types of internal argument – restricted and unrestricted arguments, where only the latter have primary object properties – is as follows. First, examples like (4c) show that reciprocalization (the formation of a derived stem by attaching the reciprocal suffix

-an-a to a verb stem) is sensitive to the distinction between restricted and unrestricted arguments, since only unrestricted arguments can be bound to the logical subject in this word formation operation. Therefore, the distinction between these two types of arguments must be available at the word formation stage in which reciprocalization occurs. Second, reciprocal verb forms can undergo a highly productive word formation process that turns verbs into nouns through the affixation of the suffix *idwe/edwe* to a verb stem. Example (6) illustrates the use of a noun consisting of the reciprocal stem *si-an-a* 'leave-RECIP' and this nominalizing suffix in a sentence (Alsina, 2001b: 364):

(6) Ma-si-an-idwe a adani
6-leave-RECIP-NOM 6.ASSOC 2.enemies
a-ma-sangalats-a.
6.SUBJ-HABIT-please-INDIC
'The event of enemies leaving each other is pleasing.'

The nominalized reciprocal in (6) has a noun class marker (*ma-*), it takes a complement (*a adani*) that is expressed the way complements of nouns are expressed (introduced by an associative marker that agrees with the head noun of which it is a complement), and it functions as the head noun of the subject NP, all of which shows that it is a noun. Nominalization preserves the argument structure of the base stem, since the arguments of the reciprocal verb stem are still expressed in the nominal form. However, the grammatical function of these arguments is different depending on whether the predicate is verbal or nominal: the subject of the verbal form corresponds to an oblique (with the associative marker) of the nominal form. If we assume that the argument structure is the syntactic information about the arguments of a predicate that is common to the various realizations of a predicate (active, passive, nominal, etc.), it follows that the nominalization process accesses the argument structure, but not the associated grammatical functions, of the reciprocal verb stem.

Thus, we can conclude that the reciprocal morpheme performs an operation on the argument structure of the predicate it attaches to (see Alsina, 2001b for further evidence in support of this conclusion). Furthermore, if the reciprocal morpheme, which performs an operation on argument structure, is sensitive to the distinction between restricted and unrestricted object, it follows that this distinction is present at the level of argument structure. Since this distinction is not semantic, but syntactic, we conclude that argument structure is a syntactic structure, as it includes syntactic information.

Accounting for Morphosyntactic Alternations

One of the important roles of argument structure is in accounting for alternations in the morphosyntactic expression of arguments: for example, the fact that the patient argument in (5) can alternatively be expressed as an object NP or as an object marker in the simple active structure, as the subject of the passive form, and as the subject of the reciprocal form, or that, in contrast with this, the patient argument in (4) can only be expressed as an object NP, lacking all the alternative forms of expression just noted. For this purpose, a linking theory is needed, a theory that constrains the possible correspondences between arguments (at argument structure) and forms of expression, which includes grammatical functions, grammatical case features, position in phrase structure, etc. In what follows, I will illustrate how a theory of argument structure, combined with a linking theory (based on Alsina, 2001b, 2003), can account for alternations (or lack of alternations) such as we have seen in the previous paragraphs.

In accordance with what has been said so far, we can assume that argument structure is a list of arguments ordered by prominence. The external argument, of those verbs that have one, is distinguished from the rest of arguments by a specific feature: [Ext]. (Oblique arguments, those that are typically introduced by semantically contentful adpositions or case markers, are given a separate treatment and will not be considered here.) Internal arguments are those that are neither external arguments nor oblique arguments. The linking principles that associate arguments with grammatical functions can be formulated as follows:

(7) Linking principles:
a. Map an external argument onto a subject.
b. Map an internal argument onto a direct function.

The idea in (7b) that an internal argument maps onto a direct function, a class of grammatical functions that includes subject and object, is responsible for accounting for the subject/object alternation that we find in many constructions, as with active and passive. Passivization can be thought of as the operation specified by the passive morpheme (*-edw/idw*) in Chichewa that suppresses the logical subject, i.e., makes it unavailable to the linking principles (7); a suppressed argument (notated by the symbol Ø) either lacks an associated grammatical function or is expressed by means of an appropriate oblique expression. Thus, whereas the argument structure

and associated grammatical functions of an active form such as that for (5a) is as shown in (8a), the corresponding passive form, as in example (5b), is as in (8b):

```
(8) a. meny-a                 'hit < [Ext]  [ ] >'
                                      |      |
                                     subj   obj
    b. meny-edw-a (pass.)     'hit < [Ext]  [ ] >'
                                      ∅      |
                                            subj
```

The requirement that all clauses contain a unique subject (the subject condition of Bresnan and Kanerva, 1989 and others) regulates whether an internal argument maps onto a subject or an object. In the active form (8a), the internal argument cannot map onto a subject, since the structure contains another argument with the subject function. In the passive structure (8b), it must map onto the subject function, as, otherwise, the structure would lack a subject and be ill-formed.

The distinction between restricted and unrestricted arguments is represented as the presence or absence of the feature R (for restricted), respectively, on arguments at argument structure; so, a restricted argument is represented as [R] and an unrestricted argument as [ ]. This is a marked (or last resort) feature that is only used, in those languages that require it (such as Chichewa), by a principle such as the following:

(9) Restricted Argument Principle: if an argument structure contains two internal arguments with distinct mapping to morphosyntactic expressions, one of them must be [R].

The presence of the feature [R] on an argument prevents that argument from being referred to by morphologically encoded operations and requires the corresponding NP to linearly follow a sister NP. Morphologically encoded operations are specifications conveyed by a morpheme, such as agreement, pronominal incorporation, and operations on argument structure (e.g., reciprocalization or causativization). Taking the feature [R] to be a last resort feature, it follows that an argument structure with a single internal argument will not contain an [R] argument. Therefore, the structures in (8) lack such an argument. On the other hand, the argument structures corresponding to (4), which clearly have two internal arguments, have to include an [R] argument in order to comply with (9). Thus, the argument structure and associated grammatical functions of (4a) is as shown in (10), where, according to standard assumptions about the ranking of arguments, the most prominent argument is the agent, the second in prominence is the beneficiary and the lowest is the patient.

```
(10) meny-er-a (appl.)'hit < [Ext]  [ ]  [R] >'
                              |      |     |
                             subj   obj   obj
```

As a language-particular constraint, roles such as beneficiary, goal, and agent cannot be restricted arguments in Chichewa. Therefore, in (10) the beneficiary is the unrestricted argument and the patient is the [R] argument. In the presence of an external argument linked to the subject function, both internal arguments map onto object functions. Now, since they differ at the level of argument structure by the presence or absence of the feature R, their morphosyntactic properties will be different.

When both objects in (10) are expressed as NPs, the restricted argument is constrained to follow the other object NP, giving the result that the beneficiary NP precedes the patient NP, as seen in (4a). If the verb includes an object marker, it must correspond to the beneficiary (the unrestricted argument), given that restricted arguments cannot be referred to by a morphologically encoded operation such as that encoded by an object marker. If the verb is passivized, making the external argument unavailable for the subject function, only the beneficiary can map onto the subject function, as shown in (4b), since the subject is always referred to by some morpheme, be it an agreement or pronominal affix in finite forms or the nonfinite morphology in nonfinite forms which licenses a nonovert subject. The operation of reciprocalization, illustrated in (4c), involves the binding or co-linking of the logical subject and another argument of the same argument structure so that both bound arguments map onto the same grammatical function. As it is a morphologically encoded operation, it cannot involve the patient argument of (4c), since it is a restricted argument, as indicated in (10): the binding of the reciprocal morpheme must involve the beneficiary role.

Aristotle and Linguistics

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

The study of language has always had two kinds of practitioners, the practical and the theoretical linguists. Aristotle was no doubt the first theoretical linguist (in addition to being the first in many other subjects), but he also contributed essentially to the development of practical linguistics. His role in the history of linguistics has been highlighted in a few publications (e.g., Seuren, 1998; Allan, 2004).

Aristotle was born in Stagira, in Ancient Macedonia, in 384 B.C.E. His father was the personal physician and a close friend of the king of Macedonia, Amyntas II. An exceptionally gifted boy to begin with, Aristotle joined Plato's Academy in Athens at the age of 17, to remain there until Plato's death in 347. Having been passed over as Plato's successor, he left Athens to live, first, in Asia Minor and then in Lesbos. In 343–342, Amyntas' son and successor, Philip II of Macedonia, invited him to come and teach his son Alexander, then 14 years old. This he did for 2 years. In 336, Alexander succeeded his father and immediately conquered the whole of Greece. Under Alexander's political protection, Aristotle returned to Athens in 335 and founded his school of philosophy, the Lyceum. There he taught until 323, when news of Alexander's death reached Athens. No longer certain of Macedonian protection, he left Athens overnight and sought refuge in Chalcis, just north of Athens, where a Macedonian garrison was stationed. One year later, in 322, he died of an intestinal disease.

His first great contribution to the study of language—not often mentioned—is the fact that he demythologized language. Rather than seeing language as a magical instrument to cast spells, entrance people, and call up past, present, and future spirits, he saw language as an object of rational inquiry, a means of expressing and communicating thoughts about anything in the world. The 'semiotic triangle' of (a) language as the expression of (b) thoughts that are intentionally related with (c) elements in the world, famously depicted in Ogden and Richards (1923: 11), is due to Aristotle. This is Aristotle's most general and perhaps also his most important contribution to the study of language, even if it is not often mentioned by modern authors, for whom it has become a matter of course that language can be seen as a valid object of rational inquiry.

In a more analytical sense, Aristotle's role in the development of linguistics is in large part due to his theory of truth. For him, truth and falsity are properties of either thoughts or sentences. A classic statement is (*Metaphysics* 1027b25):

> For falsity and truth are not properties of actual things in the world (so that, for example, good things could be called true and bad things false), but properties of thought.

A few pages earlier, he defines truth as follows (*Metaphysics* 1011b26):

> We begin by defining truth and falsehood. Falsehood consists in saying of that which is that it is not, or of that which is not that it is. Truth consists in saying of that which is that it is, or of that which is not that it is not.

Here Aristotle introduces *not* as a simple truth-functional inverter of truth values: a toggle between true and false. This has momentous consequences.

Aristotle's truth theory is known as the correspondence theory of truth, in that it requires a correspondence between what is the case in the world on the one hand and what is said or thought on the other. To make this notion of correspondence more explicit, some form of analysis is needed. Aristotle made a beginning with that. He analyzes the 'world' as consisting of things that are named by any of the 10 categories substance, quantity, quality, relation, place, time, position, state, action, or affection (*Categories* 1b25–30). Within the category 'substance,' there is a hierarchy from the primary substances (individual existing entities) through a range of secondary substances, from species and genus to any higher order. The secondary substances together with the remaining 9 categories are properties or things that things are ("everything except primary substances is either predicable of a primary substance or present in it"; *Categories* 2a33).

On the other hand, he analyzes sentences as resulting from the application of a *katêgoroúmenon* (Latin *praedicatum*) to something. The something to which the predicate is applied he calls *hypokeímenon* (literally 'that which underlies'; Latin *subiectum* or *suppositum*). Primary substances (entities) can be the object only of predicate application – that is, can only be *hypokeímena* (*Categories* 2b39–40). All other things can be either *hypokeímena* or properties, denoted by a predicate. Yet in orderly talk about the universe, it is proper to take lower categories of substance as the things predicates apply to and reserve predicates themselves for the denoting of higher-order substances and other categories of being (*Categories* 3a1–5).

The combination of a predicate with a term denoting the *hypokeímenon* Aristotle calls *prótasis* (Latin *propositio*). A proposition is true just in case the property assigned to the *hypokeímenon* actually adheres to it; otherwise it is false. Moreover, a true proposition is made false, and vice versa, by the prefixing of *not* ("it is not the case that"). The term *prótasis* occurs for the first time on the first page of *Prior Analytics*, which contains his doctrine of syllogisms (*Prior Analytics* 24a16):

> A proposition (*prótasis*) is an affirmative or negative expression that says something of something.

A proposition is divided into terms (*Prior Analytics* 24b16):

> A term (*hóron*) I call that into which a proposition is analyzed, such as the predicate (*katêgoroúmenon*) and that to which the predicate is applied.

One notes that Aristotle lacked a word for what we call the subject term of a sentence. During the late Middle Ages, the Latin *subiectum* began to be used in that sense—an innovation that has persisted until the present time (Seuren, 1998: 121–124).

This was the first semantic analysis of sentence structure in history, presaged by, and probably unthinkable without, Plato's incipient analysis of sentence meaning in his dialogue *The Sophist*. It is important to note that Aristotle's analysis of the proposition does not correspond to the modern syntactic analysis in terms of subject and predicate, but rather to what is known as topic-comment analysis. The identification of Aristotle's sentence constituent for the denoting of a *hypokeímenon* with "grammatical subject," characterized by nominative case, and of Aristotle's predicate with "grammatical predicate," may have been suggested by Aristotle, as when he says that a morphological verb "always is a sign of something said of something else" (*On Interpretation* 16b7). But it was carried through systematically a few decades after Aristotle's death by the linguists of Alexandria, whose task it was to develop teaching material for the Egyptian schools where local children had to learn Greek in the shortest possible time (Seuren, 1998: 21–22). Unfortunately, this identification was, though convenient, rash and ill-considered. It persisted more or less unchallenged until the middle of the 19th century, when some, mostly German, scholars discovered that the Aristotelian subject–predicate distinction does not coincide with the syntactic subject–predicate analysis universally applied in linguistics. For in actual discourse, very often what should be the subject according to Aristotle's definition is not the subject recognized in grammatical analysis, and likewise for the predicate. Steinthal, for example, observed (1860: 101–102):

> One should not be misled by the similarity of the terms. Both logic and grammar speak of subject and predicate, but only rarely do the logician and the grammarian speak of the same word as either the subject or the predicate. . . .Consider the sentence *Coffee grows in Africa*. There can be no doubt where the grammarian will locate subject and predicate. But the logician? I do not think the logician could say anything but that 'Africa' contains the concept that should be connected with 'coffee grows'. Logically one should say, therefore, 'the growth of coffee is in Africa'.

Observations like this gave rise to a long debate, which lasted more than 80 years. At the end, it was decided to keep the terms subject and predicate for the syntactic analysis and speak of topic and comment for the semantic analysis in the Aristotelian sense (see Seuren, 1998: 120–133 for a detailed discussion).

Syntax, in the modern sense, is largely absent from Aristotle's writings. He does, however, distinguish between different sentence types (*On Interpretation* 17a1–12):

> Every sentence is meaningful, not in virtue of some natural force but by convention. But not all sentences are assertions, only those in which there is question of truth or falsity. In some sentences that is not so. Wishes, for example, are sentences but they are not true or false. We will leave all other sentence types out of consideration, as they are more properly studied in rhetoric or poetics. But assertions are the topic of the present study [i.e., logic]. The primary assertive sentence type is the simple affirmation, the secondary is the simple negation. All other, complex, assertions are made one by conjunction. Every assertion must contain a verb or a conjugated form of a verb. For a phrase like "man" is not yet an assertion, as long as no verb in the present, past, or future tense is added.

Some word classes are already there. Thus, at the outset of *On Interpretation*, he defines *ónoma* (noun) as "a stretch of sound, meaningful by convention, without any reference to time and not containing any internal element that is meaningful in itself" (*On Interpretation* 16a19–21). *Rhêma* (verb) is defined as "that which, in addition to its proper meaning, carries with it the notion of time, without containing any internal element that is meaningful in itself; it always is a sign of something said of something else" (*On Interpretation* 16b6–8). In his *Rhetoric*, at 1406a19, Aristotle uses the term *epítheton* for adjective. All other terms for word classes are of a later date, with many of them having been created by the Alexandrian linguists.

The term *ptôsis* is found relatively frequently, in the sense of nominal or verbal morphological modification, as in *Categories* 1a13–15: "Things are said to be named 'derivatively' when they derive their name from some other word that differs in morphological form (*ptôsei*), such as the grammarian from the word *grammar* or the courageous from the word *courage*." The literal meaning of *ptôsis* is 'fall' (Latin: *casus*). Its use in the sense of morphological modification is based on the metaphor that the word 'as such' stands upright (in the 'upright case' or *orthê ptôsis*; Latin: *casus rectus*). Its other falls are represented by forms that are modified morphologically according to some paradigm. The Alexandrians began to reserve the term *ptôsis* for the nominal cases of *nominative* (the form of your own name), *genitive* (the form of your father's name), *dative* (the name of the person you give something to), *accusative* (the name of the person you take to court), and *vocative* (the name of the person you call). These terms smell of the classroom, not of philosophy.

To be "subject to contradiction by scholars" is, as W. V. Quine warns us, "the penalty for attributions to Aristotle" (Quine, 1960: 199). A case in point are the views that have been attributed to Aristotle on the basis of the first chapter of his treatise *De interpretatione*, the first half of which – i.e., if we leave aside the opening lines of the chapter, the passage from 16 a 3 to 16 a 8 – has rightly been called "the most influential text in the history of semantics" (Kretzmann, 1974: 3). In 1974 two articles appeared, in one of which this text is alleged to be "the only passage of some length in the known works of Aristotle which contains a theory of meaning" (Gyekye, 1974: 71), whereas in the other we are told that "it is not even a sketch of a general theory of meaning" (Kretzmann, 1974: 5). It can be summarized as follows: The expressions of spoken language are symbolized by the expressions of written language and are themselves symbols, or signs, of certain "affections in the soul" (16 a 3–4, cf. 6–7; Ackrill, 1963: 43), which, for their part, are likenesses of things. While these mental affections, of which linguistic expressions are signs in the first instance, as well as the things they are likenesses of are the same for all men, linguistic expressions are not.

According to the traditional interpretation of the text in question (for which see Weidemann, 2002: 134–151; for other texts relevant to Aristotle's theory of language cf. Ax, 1992 and Weidemann, 1996), by saying that mental affections are what linguistic expressions are "in the first place signs of" (16 a 6; Ackrill, 1963: 43), Aristotle implies that linguistic expressions are in the second place signs of the things of which the mental affections they primarily signify are likenesses. Interpreted in this way, our text does indeed sketch out a semantic theory.

At first sight this theory might remind a modern reader of the sort of 'uncritical semantics' described by Quine as "the myth of a museum in which the exhibits are meanings and the words are labels" (Quine, 1969: 27). That Aristotle is not committed to this "mentalistic myth of the meaning museum" (Quine, 1969: 30), however, is shown by the way in which he explains what it is for spoken words to signify something. A spoken word, he points out in *De interpretatione* 3 (16 b 20–21), signifies something by virtue of the fact that "the speaker arrests his thought and the hearer pauses" (Ackrill, 1963: 45). As the passage in Plato's *Cratylus* to which Aristotle is alluding here (437 a 4–5) makes clear, it is the thing referred to by a word at which, according to Aristotle, "the speaker arrests his thought" and upon which "the hearer pauses." This answers the question in what sense the mental affections mentioned in the first half of *De interpretatione* 1, which in the second

The term *ptôsis* is found relatively frequently, in the sense of nominal or verbal morphological modification, as in *Categories* 1a13–15: "Things are said to be named 'derivatively' when they derive their name from some other word that differs in morphological form (*ptôsei*), such as the grammarian from the word *grammar* or the courageous from the word *courage*." The literal meaning of *ptôsis* is 'fall' (Latin: *casus*). Its use in the sense of morphological modification is based on the metaphor that the word 'as such' stands upright (in the 'upright case' or *orthê ptôsis*; Latin: *casus rectus*). Its other falls are represented by forms that are modified morphologically according to some paradigm. To be "subject to contradiction by scholars" is, as W. V. Quine warns us, "the penalty for attributions to Aristotle" (Quine, 1960: 199). A case in point are the views that have been attributed to Aristotle on the basis of the first chapter of his treatise *De interpretatione*, the first half of which – i.e., if we leave aside the opening lines of the chapter, the passage from 16 a 3 to 16 a 8 – has rightly been called "the most influential text in the history of semantics" (Kretzmann, 1974: 3). In 1974 two articles appeared, in one of which this text is alleged to be "the only passage of some length in the known works of Aristotle which contains a theory of meaning" (Gyekye, 1974: 71), whereas in the other we are told that "it is not even a sketch of a general theory of meaning" (Kretzmann, 1974: 5). It can be summarized as follows: The expressions of spoken language are symbolized by the expressions of written language and are themselves symbols, or signs, of certain "affections in the soul" (16 a 3–4, cf. 6–7; Ackrill, 1963: 43), which, for their part, are likenesses of things. While these mental affections, of which linguistic expressions are signs in the first instance, as well as the things they are likenesses of are the same for all men, linguistic expressions are not.

According to the traditional interpretation of the text in question (for which see Weidemann, 2002: 134–151; for other texts relevant to Aristotle's theory of language cf. Ax, 1992 and Weidemann, 1996), by saying that mental affections are what linguistic expressions are "in the first place signs of" (16 a 6; Ackrill, 1963: 43), Aristotle implies that linguistic expressions are in the second place signs of the things of which the mental affections they primarily signify are likenesses. Interpreted in this way, our text does indeed sketch out a semantic theory.

At first sight this theory might remind a modern reader of the sort of 'uncritical semantics' described by Quine as "the myth of a museum in which the exhibits are meanings and the words are labels" (Quine, 1969: 27). That Aristotle is not committed to this "mentalistic myth of the meaning museum" (Quine, 1969: 30), however, is shown by the way in which he explains what it is for spoken words to signify something. A spoken word, he points out in *De interpretatione* 3 (16 b 20–21), signifies something by virtue of the fact that "the speaker arrests his thought and the hearer pauses" (Ackrill, 1963: 45). As the passage in Plato's *Cratylus* to which Aristotle is alluding here (437 a 4–5) makes clear, it is the thing referred to by a word at which, according to Aristotle, "the speaker arrests his thought" and upon which "the hearer pauses." This answers the question in what sense the mental affections mentioned in the first half of *De interpretatione* 1, which in the second

Figure 1 Semiotic triangle of Aristotle's theory of meaning. Adapted from Weidemann, 2002: 149 with permission.

half of this chapter are called thoughts (cf. 16 a 10, 16 a 14), are likenesses of things, on the one hand, and, on the other, that which is primarily signified – or symbolized – by linguistic expressions. The words we utter, Aristotle wants to say, refer to the things meant by them by expressing thoughts, which represent these things in our mind to the effect that to think these thoughts is nothing but to mean the things they represent (cf. Weidemann, 2001).

The semantic theory according to which words have a meaning insofar as thoughts are expressed and things are referred to by them so that to think the thoughts they express is to mean the things they refer to may be illustrated, following H.-H. Lieb (cf. Lieb, 1981: 148), by means of two interrelated semiotic triangles (**Figure 1**).

As for Aristotle's claim that, unlike things and mental affections, linguistic expressions "are not the same for all men" (*De interpretatione* 1, 16 a 5–6; Ackrill, 1963: 43), it has to be understood as underpinning his claim made in *De interpretatione* 2 (cf. 16 a 26–29) that linguistic expressions are symbols – i.e. conventional signs as opposed to natural ones – of what they signify. Being symbols, the expressions of spoken language can be written down, whereas non-linguistic sounds are "inarticulate" (Ackrill, 1963: 44) – *agrammatoi* (16 a 28–29) – in the sense of being "unwritable" (Kretzmann, 1974: 17) and "unspellable" (Arens, 1984: 40, 87). Aristotle's insistence on the identity of things and thoughts for all men must not be misunderstood. Far from taking the strange view "that all men meet the same things or have the same thoughts" (Ackrill, 1963: 113), he simply stresses the fact that the members of different linguistic communities can, using their different vocabularies, express the same thoughts and mean the same things.

In at least one respect Aristotle's theory is unsatisfactory. For his notion of thought is ambiguous in that on the one hand, being mental affections, thoughts are individually distinct acts of thinking, whereas on the other hand, being the same for all men, they are the objective contents of such acts of thinking. It is to the credit of the Stoics that in the semantic theory they developed such an ambiguity is consciously avoided.

Stoic semantics is centered on what the Stoics called – using as a technical term a word whose literal translation is 'sayable' (cf. Long and Sedley, 1987a: 195–202) – a *lekton*. As we know from Sextus Empiricus and Diogenes Laertius, who report identical definitions, the Stoics defined the notion of *lekton* by saying that a *lekton* is "what subsists in accordance with a rational impression" (ibid.: 196, §§ 33C, 33F), a "rational impression" being, as Sextus adds, "one in which the content of the impression can be exhibited in language" (ibid., § 33C). This report is supplemented by the information, also given by Sextus, that in the opinion of the Stoics "three things are linked together, what is signified (*to sēmainomenon*), that which signifies (*to sēmainon*), and the name-bearer (*to tynchanon*). That which signifies," Sextus continues, "is an utterance [...]; what is signified is the specific state of affairs revealed by the utterance, which we apprehend as it subsists in accordance with our thought, whereas it is not understood by those whose language is different, although they hear the utterance; the name-bearer is the external object [...]. Of these, two are bodies, the utterance and the name-bearer; but one is incorporeal, the state of affairs signified and sayable (*lekton*)" (ibid.: 195–196, § 33B; slightly modified following Long, 1971: 76–77).

As we can learn from the two texts just quoted, a *lekton* is the meaning of a linguistic expression in the sense of being the objective content of the respective acts of thinking performed by a speaker who utters the expression in question with the intention to say something, and a hearer who understands what the speaker intends to say.

It should be noticed that it is not linguistic expressions of any sort whatever that have a meaning in the sense of signifying a *lekton*, but only predicate (and perhaps also subject) expressions, which signify what is called an incomplete *lekton*, on the one hand, and sentences, which signify a so-called complete *lekton*, on the other hand. (Whether there are

incomplete *lekta* signified by subject expressions is a matter of dispute; cf. Gaskin, 1997 versus Long and Sedley, 1987a: 200–201.) Among the class of complete *lekta* the most important subclass is the class of those, named *axiōmata* by the Stoics and regarded as the bearers of truth and falsity, which are signified by statement-making sentences. Since an *axiōma* shares features of both the linguistic sense of a statement-making sentence and its propositional content, the Stoic term, which Long and Sedley have translated, *faute de mieux*, by "proposition" (cf. Long and Sedley, 1987a: 205–206), has no exact modern equivalent.

In relation to Aristotle, who lacks the notion of *lekton*, "the Stoics can be interpreted as filling a gap in his most celebrated doctrine of meaning" (ibid.: 201), thereby making an outstanding contribution to the development of the theory of language.

Armenia: Language Situation

A Gevorgyan, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Armenia is a highly homogenous country, with 98% of the population speaking the official language of the state, Armenian, as their native tongue. Eastern Armenian, the standard used as an official language, is characterized by a highly developed system of literary norms. The other literary standard of Armenian, Western Armenian, is spoken by the descendants of Armenians, who fled Western Armenia (now Turkey) during the genocide of 1915 and settled outside Armenia. Yet another literary standard, Grabar (the Old Written Armenian), is used in Armenian Church services.

Minority languages in Armenia (the speakers of which constitute 2% of the population) include Russian, with 29,500 speakers (more than 50% of whom are ethnic Armenians); Kurmanji, the dialect of Kurdish spoken by Yezidis (31 800) and Kurds (1300) (although the language spoken by Yezidis is technically a variant of Kurmanji, they prefer to call the language they speak Yezidian and distance themselves from Kurds both by ethnicity and language); Neo-Assyrian (Assyrian Neo-Aramaic), spoken by some of the 3500 Assyrians; Greek (1300 speakers); Ukrainian (818 speakers); and some others with even fewer speakers. Most of the minority ethnic groups immigrated into Armenia about two to three centuries ago and have been able to maintain and develop their language and culture, thanks to their compact settlement as well as the efforts of the Soviet government, whose policies greatly supported ethnic minorities. After Armenia achieved independence in 1991, despite its deteriorated economical potential, the Armenian government continued to make efforts to continue supporting the preservation of the languages and cultures of minorities, especially since three of them (Assyrian Neo-Aramaic, Yezidian, and Kurdish) are not principal languages/cultures in any country. Almost all the speakers of minority languages are bilingual, speaking Armenian, Russian, or both, besides their mother tongue, which frequently serves for home use.

The language situation in Armenia is marked by diglossia, whereby the standard Eastern Armenian is used for written communication, formal and official situations, and in education, while regional dialects, some of which can be mutually unintelligible, are used for everyday and domestic communication. Another characteristic of the language situation in Armenia is Russian-Armenian bilingualism, which involves about 90% of the adult population. Historically, Russian has had a special status in Armenia, as in all the former Soviet republics. In fact, the prestige and functionality of Armenian had been gradually declining before independence. Since independence, Armenian has become the main language of instruction at all levels of education as well as that of official communication and broadcasting.

Among foreign languages, Russian instruction is introduced in the second grade of elementary school, and English (less frequently French or German) is introduced in the third grade. Instruction in both foreign languages continues throughout the first years of college. In recent years, English has increasingly gained ground.

'Armenian' actually refers to several languages, including Standard Eastern and Western Armenian, Middle (/Medieval/Cilician) Armenian, and Classical Armenian, as well as Zok, formerly spoken by the Armenian inhabitants of southeastern Nakhichevan; Kistinək, spoken by the Armenian inhabitants of Musaler, Turkey; Kesbənuək, spoken by the Armenian inhabitants of Kesab, Syria; Homshetsma or Homshetsnak (referred to as Hemşince in Turkish), spoken by the Hemshinli of northeast Turkey and the Hamshen Armenians of the Black Sea coastal

regions of Abkhazia and Russia; and dozens of other mutually unintelligible variants of Armenian originally spoken in Turkey, Armenia, Azerbaijan, Iran, Georgia, Abkhazia, Russia, and Israel. Lomavren, the language of the Bosha (or Posha) gypsies of Turkey and Armenia, draws its grammar from the Erzerum dialect of Armenian but its lexicon is mostly of Indic origin; it therefore is not clear whether or not the language should be classified as a form of Armenian. All employ the Armenian alphabet (created by Mesrob at the beginning of the 5th century) except for the Turkish forms of Homshetsma, which normally appear only in oral contexts, but in recent years have begun to show up in Turkish orthography in collections of word lists from minority groups in Turkey, lyrics on CDs, and the like.

Armenian belongs to the Indo-European family, and is commonly believed to be most closely related to Greek and Indo-Iranian. (For instance, all three share a prohibitive particle **me:* (Greek *me:*, Sanskrit *ma:*, Armenian *mi*) and the imperfect third-person singular augment **e-* (as in Greek *e-pher-e*, Sanskrit *a-bhar-a-t*, Armenian *e-ber* '(s)he/it carried'). Many more such parallels are discussed in Clackson, 1994.) Because of its many loans from various Middle Iranian languages, especially Parthian, Armenian was thought to be an Iranian dialect until Heinrich Hübschmann demonstrated in 1875 that it was a distinct branch of the Indo-European family. Scholars disagree on how the Armenians came to historical Armenia, the eastern half of present-day Turkey centered around Lake Van and Mount Ararat; some believe they came southward from the Russian steppe, others believe they and the Hittites came eastward from Greece, and others suggest they moved only a short distance from an original Indo-European homeland in the Transcaucasus. It is most likely that this settlement occurred in the second millennium B.C. The earliest mentions of the Armenians occur in the inscriptions of the Achaemenid Persian king Darius (6th century B.C.) and the Greek historian Herodotus (5th century B.C.)

The earliest written records of the Armenian language date from the 5th century A.D. shortly after the conversion of the Armenians to Christianity in the 4th century led to the creation of an Armenian alphabet by Mesrob around 401 and a systematic program of translating the books of the Bible. The language of the earliest translations was Classical Armenian (also called *grabar*, 'written [language]'), which continued as the preferred literary form of Armenian until the 19th century, when it was supplanted by the three modern literary dialects.

In linguistic terms Armenian is notable for its significant divergences from Proto-Indo-European, particularly in terms of pronunciation and vocabulary. Some of the more striking phonological changes are the development of a rich set of affricates (*ts*, *dz*, etc.), the loss of final syllable rimes (e.g., PIE **worg^{j}om* 'work' > Classical Armenian *gorts*), the change of initial **dw* to *erk-* (e.g., PIE **dwo:* '2' > Classical Armenian *erku*), and the change of original **w* to *g*. Most striking in the vocabulary of Armenian is the rarity of words inherited from Indo-European and the overwhelming predominance of words of unknown origin. Unsurprisingly, native IE words survive primarily in the core vocabulary: *mayr* 'mother' < **ma:ter*, *hayr* 'father' < **pater*, *k^{h}oyr* 'sister' < **swesor*, *kov* 'cow' < **gwows*, *tun* 'house' < **domos*, *em* 'I am' < **esmi*. The remainder of the lexicon is drawn primarily from Parthian, and to a lesser extent Greek and Syriac (q.v. Hübschmann, 1895); several hundred and perhaps as many as several thousand words are of unknown origin, most likely having come from Urartian, Hurrian, and other now-extinct autochthonous languages. Armenian also incorporated large numbers of Arabic words following the expansion of the Arabs in the Middle East in the 7th century, and the spoken language absorbed thousands of Turkish words following the arrival of Turkic tribes in Anatolia beginning in the 11th century.

Though there are dozens of mutually unintelligible varieties of Armenian, all share certain features. Proto-Armenian had four verbal conjugations, characterized by theme vowels -e-, -i-, -ɑ-, and -u- (beɾ-e-m 'I carry', χawsim 'I speak', χndam 'I rejoice', zgen-u-m 'I wear'); most modern dialects (including the Western and Eastern literary languages) have completely or partially lost the -u- conjugation, and standard Eastern Armenian has merged the -i- conjugation into the -e- conjugation. There were originally three morphologically distinct sets of personal endings for verbs – present, imperfect, and aorist – which were used in combination with additional tense and aspect markers to form the various tenses and moods. The system of nominal morphology in Proto- and Classical Armenian was rich, preserving the IE nominative, accusative, genitive, dative, instrumental, ablative, and locative cases in both singular and plural (but the IE dual was lost); there were at least eight different declensions, distinguished primarily by different theme vowels. This system was significantly reduced by the medieval period; Middle Armenian and the modern varieties now use the singular endings for the plural as well, and have only one productive declension, formed from parts of the original -i- and -o- declensions. With the exception of pronouns, the inventory of cases has significantly reduced as well: the accusative has merged with the nominative, and the genitive with the dative. Proto-Armenian

had several participial forms, but only two of these survive into the modern period: the original past participle -eal is now -el in the Eastern dialects, and the original present participle -oʁ is now used as a present participle and for relativizing subjects of subordinate clauses, as in the following Standard Western Armenian example:

ɑjn	kʰiɾkʰ-ə	kʰən-oʁ	gin-ə
that	book-def.	buy-pres.ppl.	woman-def.

'the woman that is buying that book'

The Western dialects have replaced -eal with -ats (> -adz) for past participles; all modern dialects also use the -ats participle to relative non-subjects of subordinate clauses, as in the following Western example:

(kʰu)	kʰən-ɑdz	kʰiɾkʰ-ətʰ
2sg$_{GEN}$	buy-past.ppl.	book-2sg$_{POSS}$

'the book that you (have) bought'

Most of the changes between Classical and Modern Armenian first appear in the medieval period in Middle Armenian documents, associated with the Armenian kingdom of Cilicia, which flourished from the 11th to 15th centuries A.D. in what is now south-central Turkey. Middle Armenian is generally Western in character, though it shares many features with Eastern dialects as well. It inverts the pronunciation of the Classical Armenian plain voiced and voiceless stops (e.g., berem 'I carry' > perem, pat 'wall' > bad), a feature that is preserved in the modern Cilician dialects of Zeytun and Hadjin but differs from the Western and Eastern literary varieties (Eastern preserves the Classical system [bɛɾɛm]; Western devoices and aspirates the original voiced series [pʰɛɾɛm]). The Cilician kingdom was in close contact with several Crusader kingdoms; as a result, it borrowed a significant number of words from Crusader French, most famously what comes out as the standard Western form for 'mister', *baron*.

In the 19th century Armenian nationalists became interested in developing a literary form of the modern language. This was brought about by excising most Turkish forms from the regional dialects and replacing them with new borrowings from the classical language. The intellectual center around which the new Western literary language was organized was Constantinople (modern Istanbul), though many features of the standard dialect (including the pronunciation of the consonants) do not come from the Armenian dialect originally spoken there. The same holds for Eastern Armenian with respect to Erevan. The relationship between the two modern literary dialects is somewhat complicated; there are many grammatical differences (e.g., W gə siɾɛm vs. E sirum

Table 1 The Armenian alphabet, with IPA equivalents for eastern pronunciation

Ի	i	Ո	(v)o	Օ	ɔ
Լ	l	Չ	tʃʰ	Ֆ	f
Խ	χ	Պ	p		

ɛm 'I love', W bidi siɾɛm vs. E kəsiɾɛm 'I will love' (note that the same form is used for the present in W and the future in E) and lexical differences (e.g., W dʒɛɾmɑg vs. E spitɑk 'white'; W hɔs vs. E ɛstɛʁ 'here', W bɛdkʰɑɾɑn vs. E zukʰɑɾɑn 'bathroom', W hɑvgitʰ vs. E dzu 'egg'), and most Western speakers have difficulty understanding Eastern, but many Eastern speakers are relatively comfortable with the Western dialect. This asymmetry in mutual intelligibility most likely results from the fact that large numbers of speakers of Western dialects fled to Eastern Armenia following the Russo-Turkish war in 1828 and the Turkish Genocide in 1915–1920, whereas before the fall of the Soviet Union in 1991 most Western Armenians had little or no exposure to Eastern Armenian. The fact that there is some mutual intelligibility in both directions can also be linked to the fact that the literary dialects tend to borrow the same forms from Classical Armenian, and (at least in recent decades) employ the same newly coined words.

The destruction of the Armenian homeland and more than a million Armenians by the Ottoman government in 1915–1920 rendered most nonstandard varieties of modern Armenian moribund; with few exceptions the Armenians in the diaspora (primarily Lebanon, France, and notably in the Los Angeles area of the United States) speak only Standard Western Armenian. There were approximately 6.8 million speakers of Armenian in 1996, but all varieties of the language except for Standard Eastern Armenian are in immediate danger of extinction as very few diaspora Armenians under the age of 30 speak the language fluently.

Whereas Classical Armenian was relatively Indo-European in its syntactic and morphological structure, all varieties of Modern Armenian are typologically much closer to Turkish and the Balkan languages. Compare, for instance, the formation of relative clauses, exemplified by 'I saw the bird that was singing in

the tree': Classical – tesi əz-tʰərtʃʰun-ən oɾ eɾɡɛɾ i veɾaj tsaɾ-oj-n (I.saw specific-bird-definite that was.singing in on tree-genitive-definite), Western – dzaɾ-i-n vəɾa jɛɾkʰɔʁ tʰərtʃʰun-ə dɛsa (tree-gen.-def. on singing bird-def.I.saw). Western Armenian has undergone additional influence from Turkish and Greek (cf. sdɛpʁin 'carrot', istakʰɔz 'lobster', bantʰɔg 'hotel'), whereas Eastern Armenian has been heavily influenced by Russian (e.g., the standard form for 'potatoes' is kʰaɾtʰɔfli, and the word for 'gay' is ɡalubɔj, from the Russian word originally meaning 'sky blue'; the native word for 'blue', kapujt, cannot be used in this sense).

Armstrong, Lilias Eveline (1882–1937)

B S Collins, Leiden University, Leiden, The Netherlands
I M Mees, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Lilias Eveline Armstrong was born in Salford, England, in 1882, the daughter of a minister of religion. After taking her B.A. at Leeds in French and Latin, she went on to a highly successful career as a teacher of French. She abandoned school teaching in 1918 to join Daniel Jones's department of phonetics at University College London, initially as a temporary lecturer, but rapidly rising to become Senior Lecturer, and eventually Reader in Phonetics, before early death cut short her career. In 1926, Armstrong married the Russian linguist Simeon K. Boyanus (1871–1952), but continued to use her maiden name for her professional work.

Armstrong was a devoted follower of Jones, and his influence is apparent in all her writings, beginning with her *English phonetic reader* (1923). Together with her UCL colleague Ida Ward (1880–1949), Armstrong wrote a popular and influential student textbook, *Handbook of English intonation* (1926), drawing considerably on Jones's earlier theories and tone marking systems. Armstrong's interest in French bore fruit in her widely used *Phonetics of French* (1932), actually based in part on Jones's lecture notes (Collins and Mees, 1999: 278–281). Shortly afterward she co-operated with her colleague Hélène Coustenoble (1894–1962) on a more advanced work, *Studies in French intonation* (1934).

Early on, Armstrong began to show interest in non-European languages, particularly tone languages—an area of linguistics then still in its infancy. This was first evidenced by her co-authorship of *A Burmese reader* (Armstrong and Pe Maung Tin, 1925). Later she concerned herself mainly with African languages, publishing a significant description of Somali (1934) and producing the manuscript of a major work on Kikuyu (Gikuyu) (using as her informant a young student, Jomo Kenyatta, the future first prime minister of Kenya). This project was at an advanced stage, but still incomplete, when Armstrong was suddenly struck down by the illness that caused her death in 1937. The book, *Phonetic and tonal structure of Kikuyu* (1940), regarded as one of the best pioneering studies on African tone languages, was eventually completed by her London colleague Beatrice Honikman (1905–1997) and published posthumously.

Armstrong's importance in the history of British phonetics is clear from her many publications—in particular, her groundbreaking research on intonation and tone. Less obvious, but of at least equal significance, is her influence as Jones's second-in-command in the interwar years, during which she helped him build up the University College London department into what was, for a time, the most influential center of excellence worldwide for the study of phonetics.

Armstrong, Robert Gelston (1917–1987)

G T Childs, Portland State University, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Although Robert G. Armstrong began his research career as an anthropologist with a strong Marxist bent, he attenuated his theoretical concerns over time to become a fairly locally oriented researcher, restricting his scholarship after his thesis and subsequent events to Nigeria, where his contributions were considerable and probably underappreciated. The major focus of his work was on the Idoma people and their language, and he published significant works on Yoruba, Idoma, and related languages and cultures.

Born in Danville, Indiana, in 1917, Armstrong grew up in Cincinnati and graduated from Miami University in 1937. He began his graduate studies at the University of Oklahoma but transferred to the University of Chicago in 1939. His studies were interrupted by being drafted into the U.S. Army, where he served as a code clerk in Panama and in the United States for 3 years (1942–1945). He finished his dissertation in 1950, and in 1952 it was accepted. Basing himself on work by British social anthropologists (it was written during 1950 while he was at Oxford), he traced 'exploitation' in six African cultures, ranking them in an evolutionary order.

In 1953, Armstrong was set to assume a replacement position at Chicago, but his membership in the Communist Party (1939–1948) cost him the job. At the height of the McCarthy era, he lost the Chicago position at the last minute due to the direct intervention of the FBI (Stocking, 2002a, p. 9). After being denied the temporary appointment, he lived with his family and worked in his father's business for several years, during which period he was rejected for a half dozen jobs before he was finally hired in the fall of 1956 in Atlanta (where he had taught for a year in 1947–1948).

Armstrong returned to Nigeria in 1959, where he flourished, becoming closely involved with the Idoma people, with whom he had worked as part of his 1950–1952 thesis fieldwork. He came originally to study Yoruba language and law but soon expanded his study to law and performance among the Idoma, including traditional forms of verbal performance. Some of the Yoruba work resulted in publications of transcriptions of traditional oral performances, and he published widely in the area of Idoma descriptive and comparative linguistics.

From 1960 to 1962, Armstrong was field director of the West African Languages Survey and was heavily involved in its successor, the West African Linguistics Society. He served as research professor of linguistics at the University of Ibadan from 1962 to 1983, after which he went to the University of Nigeria, Nsukka, for 2 years. After his retirement, he continued his work on Idoma up until his death.

An anecdote reveals the nature of his work in Nigeria. Dancing with the young boys and girls in a rather erotic exchange, Armstrong was reproved by the more Westernized (and scandalized) members of the audience, saying that he was encouraging the old ways. Armstrong wrote in a private letter, "[T]his was my precise intention" (Stocking, 2002b: 5).

Encouraging the preservation of culture was perhaps Armstrong's greatest contribution, be it language or performance in the form of legal argumentation, song, drama, or dance. The Idoma honored him with full chiefly honors at his death with a 2-day celebration.

Arnauld, Antoine (1612–1694)

P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born in Paris on February 6, 1612, Antoine Arnauld was the son of a court lawyer. He studied philosophy, law, and theology in Paris; in 1635, he received a Bachelor's degree at the Sorbonne, and in 1641 received his degree of Doctor of Theology. He was ordained a priest in 1641. An adherent of Jansenism, Arnauld published a treatise in 1643, *De la fréquente communion*, in which he attacked Jesuit views on religion and religious practice; by that time Arnauld was commonly recognized as a leading Catholic theologian and philosopher. Arnauld went to live as a 'solitaire' in Port-Royal, where he organized teaching and where he himself taught philosophy. In 1653, Jansenism was condemned by Pope Innocent X. Arnauld replied with two pamphlets in defence of Jansenism. He lost his degree of Doctor of Theology, and left Port-Royal. In 1656, Jansenism was again condemned by Pope Alexander VII, and the French clergy drew up a formulary to be signed by all ecclesiastics. Arnauld refused and replied with three memoirs; in addition, he helped with the publication of Pascal's *Lettres provinciales*, directed against the Jesuits. In 1660, the anonymous general and rational grammar of Port-Royal (authored by Arnauld and Cl. Lancelot) appeared, testifying to Arnauld's continuing influence at Port-Royal. In 1661, Arnauld finally signed the formulary.

Under Pope Clement IX, tensions between Jansenists and Jesuits diminished, and Arnauld regained his influence in royal circles. In 1662, Arnauld published, with Pierre Nicole, the Port-Royal logic (*La Logique ou l'Art de penser*), and in 1664 he published a refutation of Calvinism (*La Perpetuité de la foy de l'Eglise catholique touchant l'Eucharistie*). Protestantism was also the target of Arnauld's 1672 book *Le Renversement de la morale de Jésus-Christ par les erreurs des calvinistes touchant la justification*. When Louis XIV started to persecute the Jansenists, Arnauld went to the Low Countries. He established himself in Brussels, where he published pamphlets against the Calvinists and the Jesuits, and where he stayed until his death on August 8, 1694. During this period of exile, Arnauld was philosophically very active; he polemicized with N. Malebranche and B. Lamy, corresponded with G. W. Leibniz, and wrote *Des Vraies et des fausses idées* (1683) and *Règles du bon sens pour bien juger des écrits polémiques dans les matières de science*. (For an overview of Arnauld's vast output, see Baudrillart, 1930: cols. 447–484.)

Arrernte

G Breen, Institute for Aboriginal Development, Alice Springs, NT, Australia

© 2006 Elsevier Ltd. All rights reserved.

Arrernte, using the most common current spelling, is the name of what was for many years, if it is not still, the most well-known Aboriginal language name in Australia. The first widely used spelling was 'Arunta,' and this is the spelling that leads to the best approximation to the pronunciation of the name ([ɒˈrəɳɖə], often [ˈarəɳɖə]) by the general English-speaking reader. The early German Lutheran missionaries introduced the spelling 'Aranda.' The spelling 'Arrernte' is that of the practical orthography most used now by writers in the language, and has acquired wide currency, for example, in the print media. The (Lutheran) Finke River Mission now uses the spelling 'Arrarnta.'

At the time of European settlement, which reached the central part of Australia in the 1870s, the Arrernte speakers occupied a large area in the southeastern part of the present Northern Territory, spilling over into Queensland and South Australia (see Figure 1). The name Arrernte (with various qualifiers) is used for several dialects of what is generally regarded as a single language, called Upper Aranda by Hale (1962), and also for another closely related language that Hale called Lower Aranda. The Upper Aranda language group includes three main subgroupings: Western, Central, and Eastern Arrernte and Anmatyerr and Alyawarr as dialects, which have of the order of a 1000 speakers each and are still being learned by children; Southern Arrernte (or Pertame), many of whose speakers now use Western Arrernte; and extinct or nearly extinct varieties, Antekerrepenh and Ayerrereng. The relationship of modern Western Arrernte to an almost extinct dialect that has been called Tyurretye Arrernte (Breen, 2001) is not clear; it could be that the latter is the original western dialect and the former is essentially Southern Arrernte. Anmatyerr and Alyawarr do not identify as Arrernte. The other language, Lower Arrernte (Hale's Lower Aranda, called Lower Southern Arrernte/Aranda by some, but Arrernt Imarnt in the dictionary that is being compiled by the author at the time of writing), had in 2004 only a couple of moderately competent, elderly speakers. The two languages, Upper and Lower Arrernte, are grouped (but not uncontroversially) with the more distantly related Kaytetye under the name Arandic (see Koch, 2004), and this is classed as a subgroup of the Pama–Nyungan family (which, again, is not universally accepted).

Study of the Arrernte language was begun after 1877, by German missionaries, notably Carl Strehlow. Strehlow's son, T. G. H. Strehlow, continued his father's study of the language and amassed a vast quantity of data, the culmination of his work being the wonderful *Songs of Central Australia* (1971). Somewhat earlier, around 1960, the linguist Ken Hale (1934–2001) had collected excellent material in most dialects. The Summer Institute of Linguistics (SIL) and other mission linguists have also worked on the languages for many years; the first substantial Western Arrernte Bible portion appeared in 1925 and there have been many other, mostly smaller, works. Substantial theses on Arrernte phonetics and grammar have been written by David Wilkins (1989), John Henderson (1998), and Victoria Anderson (2000). One of the most extensive dictionaries of any Australian language to appear to date is that of Eastern and Central Arrernte by Henderson and Dobson (1994). Smaller dictionaries are those of Alyawarr (Green, 1992) and Western Arrernte (Breen, 2000); dictionaries of Anmatyerr (a work in progress, by Jenny Green) and Lower Arrernte (Breen) are to appear in the near future. No detailed grammar has been published. Indigenous writing is in its infancy.

Table 1 gives the consonant inventory of Central Arrernte, using orthographic symbols, as typical of these languages. The basic vowel system comprises a featureless vowel, written *e*, dependent for its quality on the surrounding consonants, and a low vowel, *a*. In most dialects there is also a high front vowel, with a comparatively small functional load, and in some there may also be a high back vowel, with a small functional load, which, however, may be better analyzed as due to the effect on *e* of roundness on a following consonant. Roundness, derived from an ancestral rounded vowel, may be associated with consonant positions. A seventh consonant position, prepalatalized apical (*yt*, *yn*, *ytn*, *yl*), postulated for some dialects, may be more correctly analyzed as a palatalization feature associated with the consonant position. In other dialects, prepalatalized apicals are an allophone of phonemes in the series called apical postalveolar.

Arrernte (and also Kaytetye) are a focus of attention for linguists because of the substantial sound changes that the languages have undergone in the not too distant past. These include loss of initial syllables or their replacement by a vowel; transfer of the feature 'roundness' from the vowel to an adjacent consonant (from which it might spread or migrate) – this resulted in the earlier three-vowel inventory being reduced to two, with later expansion, as noted previously; prestopping of certain nasals; and loss (or, as

Figure 1 Locations in Australia where Arrernte and some neighboring languages are spoken. Reprinted from Green (1998), with permission.

Tap					rr	
Glide	w	h		y		r

Koch (1997) has it, neutralization) of final vowels. Orthographically, in some dialects, all words are written with final *e*, representing schwa, whereas in others, final (predictable, often optional) vowels are not written, except, as *a*, in short words, in which they may be the stressed or even the only vowel. Thus, for example, earlier **nyina-* 'sit' has become *n-* or *an-*; **ngali* 'we (dual, inclusive)' has become *il-*, *ayl-*, or

aly-; **wama* 'snake' has become *apme* or *apmwe*; and **munga* 'night' has become *ingwe*. Breen and Pensalfini (1999) have argued that, contrary to the supposed universal situation that all languages have consonant–vowel (CV) syllables and that VC syllables can occur only in a language that also has CV, CVC, and V syllables, the sole underlying syllable shape in Arrernte is VC(C). Words that are consonant-initial on the surface have an underlying initial schwa. (See Breen (2001) for a brief overview of the phonologies of the different dialects, and Koch (1997) for his view of the sound changes that have occurred.)

In phonotactics, Arrernte is atypical in Australia in that it allows monosyllabic words and (surface) word-initial consonant clusters (homorganic or heterorganic). In most dialects, the vast majority of words are vowel–initial, mostly *a*-initial (the remainder having the underlying initial schwa, which never appears utterance-initially). The definition of the concept 'word' in Arrernte is problematic; units that are clearly words, or even phrases, can be incorporated into words, dividing them into parts that are clearly less than words (see Henderson, 2003).

Grammatically, Arrernte is typical of languages of most of Australia in the following ways:

- Nouns operate in an absolutive/ergative paradigm but pronouns are nominative/accusative, except that first- and second-person singular in eastern and northern dialects distinguish intransitive subject, transitive subject, and object.
- Pronouns have three numbers – singular, dual, and plural – and in some dialects distinguish exclusive from inclusive in first-person dual and plural (whereas others have lost this distinction but retain, with no function, the old exclusive marker).
- Cases are marked by suffixation.
- There is no grammatical gender.
- The rich verbal morphology includes a variety of compound types; verb suffixation marks tense, mood, aspect, associated motion, and, optionally, number of subject.
- Reduplication, of various types, is prominent in the grammar of the major lexical categories.
- Preferred constituent order is subject-object-verb (SOV), but this is frequently varied by pragmatic factors.

There is a complex interaction between kinship and grammar, although much of this is being lost. Society was, in the recent past, organized into four sections (called 'skins' in Aboriginal English) based on a division into two patrilineal moieties superimposed on a division of alternating generations. Not long before European settlement, a further division to form eight subsections diffused from groups in the northwest, but did not reach to the easternmost or southernmost parts of the Arrernte area. Nonsingular pronouns can be marked according to the relationship of the persons concerned; thus, in Alyawarr, we have *ayla* 'we (dual, inclusive, same section),' *aylern* 'we (dual, exclusive, same section),' *aylak* 'we (dual, inclusive, same moiety but differing by an odd number of generations, as father and child),' *aylernak* (as *aylak*, but exclusive), *aylanth* 'we (dual, inclusive, different moiety, as mother and child or husband and wife),' and *aylernanth* (as *aylanth*, but exclusive). Kinship terms can be suffixed with morphemes derived from dative pronouns to indicate possessor; so, from *arreng* 'father's father and reciprocal' we can have *arrengaty* 'my father's father,' 'my son's child (I being male),' 'my brother's son's child,' and so on; *arrengangkw* 'your father's father,' etc.; *arrengikw* 'his or her father's father,' etc.; *arrengalyew* 'our father's father, we being siblings,' etc.; and *arrengalyewak* 'father's father of one of us (we being in the same moiety but differing by an odd number of generations, as father and child),' etc. This last term, *arrengalyewak*, can be used by some speakers in the singular ('father's father of one or other of us'), but others could use it only if, say, there were two people who were 'your and my father's fathers.' Each of the 27 possible suffixes can be used in this way. The following sentence is a relatively simple example in Antekerrepenh, translated by the speaker (SS means 'same section'; VOC, vocalic; ERG, ergative; 1DU, first-person dual; DAT, dative):

(1) Angkwer-ey antyeny ayn-el-ayl-ek
elder.sister-VOC old.man father-ERG-1DU.SS-DAT
aherr atw-ern.
kangaroo kill-PAST
'Well sister, old dad's killed a kangaroo.'

Another example, in Alyawarr, is from a children's story (Summer Institute of Linguistics, 1996); the stories were the result of a linguist showing the (adult) language workers a series of drawings and asking them to make a story about the drawings. The first story in the book, about three boys who got lost, had the following sentence (DM means 'different moiety'; 3PL, third-person plural):

(2) Am-ayn-ew-anth-err-then
mother-3PL-DAT-DM-PL-also
ayn-ayn-ew-anth-err-then
father-3PL-DAT-DM-PL-also
nthw-ew-anem ampa ikwer-rnem
look.for-PAST-then child 3SG.DAT-PL

This is translated as 'Their mothers and fathers looked for the children'; the boys could have been two brothers and their cross-cousin. The same kinship

terms were used with ergative marking on the following page of the story. Note that, there is no number marking, but the use of the complex kinship terms seems perfectly natural and efficient (these and other complexities of kinship grammar are as yet unpublished, but see Breen (1998) and Green (1998)).

In a narrow sense, articles can be said to be grammatical elements that in many, but by no means even most, languages encode as their core meaning the identifiability of a referent in a noun phrase. Hence, by using the English definite article *the*, the speaker implies that the recipient should be able to identify the intended referent, and by using the indefinite article *a*/~/*an,* the speaker implies that this is not necessarily the case.

In English, a noun phrase cannot simultaneously take the INDEF *a* and the DEF *the*. In this respect, the English articles behave as members of one grammatical category. The use of one member excludes the other, i.e., the members of a category are each other's paradigmatic alternatives in the same syntactic slot. In many languages, however, the two articles do not occupy the same syntactic slot, even though they may still be each other's alternatives. In, for example, Danish, the indefinite article precedes the noun as a free morpheme, whereas the definite article is suffixed to it as a bound morpheme, as shown in examples (1a) and (1b):

(1a) et barn
INDEF.NEUT child
'child'

(1b) barn-et
child-DEF.NEUT
'the child'

As with most grammatical categories, not all languages have articles – in fact, probably the majority of all languages make do without them. In those languages, a simple noun phrase can be interpreted as

Articles, Definite and Indefinite

P Juvonen, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

In a narrow sense, articles can be said to be grammatical elements that in many, but by no means even most, languages encode as their core meaning the identifiability of a referent in a noun phrase. Hence, by using the English definite article *the*, the speaker implies that the recipient should be able to identify the intended referent, and by using the indefinite article *a*/∼/*an,* the speaker implies that this is not necessarily the case.

In English, a noun phrase cannot simultaneously take the INDEF *a* and the DEF *the*. In this respect, the English articles behave as members of one grammatical category. The use of one member excludes the other, i.e., the members of a category are each other's paradigmatic alternatives in the same syntactic slot. In many languages, however, the two articles do not occupy the same syntactic slot, even though they may still be each other's alternatives. In, for example, Danish, the indefinite article precedes the noun as a free morpheme, whereas the definite article is suffixed to it as a bound morpheme, as shown in examples (1a) and (1b):

(1a) et barn
INDEF.NEUT child
'child'

(1b) barn-et
child-DEF.NEUT
'the child'

As with most grammatical categories, not all languages have articles – in fact, probably the majority of all languages make do without them. In those languages, a simple noun phrase can be interpreted as

either definite or indefinite depending on the context. So, e.g., in Finnish:

(2) Anna lukee kirja-a
Anna reads book-PART
'Anna is reading the/a book'

Languages without articles are, of course, able to express the identifiability of a referent as well as other related senses. To achieve this, a number of strategies, including word order, stress, indefinite and definite pronouns, and morphological case, can be used.

Even though both definite and indefinite articles may belong to a common category of articles in some languages, they are treated separately in the following discussions. The reasons for this have already been hinted at: a language having one type of article does not necessarily have the other. Also, the two articles in languages that have both do not always occupy the same syntactic slot.

Definite Articles

Diachronically, the most common source for definite articles in the languages of the world is a distal demonstrative (Heine *et al.*, 2002; Greenberg, 1978), with which a definite article shares a number of usage contexts. Less commonly, definite articles may develop from possessive suffixes (Schroeder, 2005) or third-person personal pronouns. Of course, these two, in turn, share a number of features with demonstratives.

Following Hawkins (1978), Himmelmann (1998: 323) illustrated the historical and pragmatic overlap between demonstratives and definite and specific articles by listing the major contexts of use for what he calls D-elements (Table 1). In a situational use, the referent of the noun phrase (NP) is present in the situation: *Give me the/~/that, book*. Demonstratives and definite articles can both be used in this kind of context, regardless of whether the referent has been mentioned earlier. In discourse deictic uses, the antecedent of the referring NP consists of a longer stretch of discourse, as when, as it were, summarizing a lengthy discussion about the reasons for global warming by *the main problem*. . . . Both definite articles and demonstrative determiners also appear in anaphoric mentions of a referent already mentioned within the current discourse, i.e., they are used in a tracking function: *I met a man yesterday [. . .] and then two hours later I came across the/~/that, guy again*. The development of a deictic demonstrative toward more article-like uses is often thought to begin as an increase in frequency in anaphoric contexts. The use of the demonstrative may further spread into contexts in which the identification of the intended referent requires utilization of knowledge of the situation and/or of the world. In recognitional uses, the referent is supposed to be known to the interlocutor by way of specific knowledge. For example, if you gave your mother a new television set for Christmas, you can bring it into a conversation by *Is the TV working as it should?* Himmelmann proposes that demonstratives in general cannot be used in the remaining two functions, the larger situation use and the associative-anaphoric use. Hence, these functions could be used as a test case for articlehood. Larger situation use refers to uses in which an entity considered to be uniquely identifiable in a given speech community is referred to for the first time within the current verbal exchange, as when talking about *the sun*, or *the King*. Uttered in Sweden, in a nonscientific context, the former will uniquely identify the star closest to Earth and the latter will uniquely identify King Carl XVI Gustaf. The associative-anaphoric use refers to first mentions of new referents within a discourse such that the referent can be identified via another, already present referent, as in *I have a bicycle, but* ***the gears*** *are out of order.*

As a demonstrative grammaticalizes toward an expected and automatized part of a nominal construction, it usually gets phonetically reduced (the English *the* < *þat*), but also, void of its original deictic meaning, it begins to mean 'identifiable' in general. By now, the erstwhile demonstrative is often recognized as a full-blown definite article that can in turn develop to a marker of specificity, and further to a mere gender marker or general marker for 'nouniness' (Greenberg, 1978).

Languages with definite articles vary as to the functions in which these can be used. Most definite articles can be used in referring expressions, especially with singular count nouns, whereas they are less common in nonreferring, e.g., predicative, constructions. In some languages, they have just reached the stage of anaphoric use, for which uses the term

Table 1 Major contexts of use for D-elements. From Himmelmann (1998: 323)

	Demonstrative pronouns	*Definite articles*	*Specific articles*
Situational	+	+	+
Discourse-deictic	+	+	+
Tracking	+	+	+
Recognitional	+	+	+
Larger situation	−	+	+
Associative-anaphoric	−	+	+
Specific-indefinite	−	−	+

'anaphoric article' is occasionally used. In yet others, they are not only used in associative-anaphoric and larger situation uses, as in English, but also in generic expressions (French, Swedish) and/or with proper names (Portuguese ***o*** *João*, ***a*** *Céu*).

As already mentioned, definite articles also vary cross-linguistically both in form (free or bound morphemes) and in placement (pre- or postposed). In some languages, the definite article cannot co-occur with demonstratives; in yet others, as illustrated by Swedish in example (3), it can:

(3)	Den här	gaml-a	tidning-en	kan	du	slänga
	DEM.NON-NEUT here	old-DEF	newspaper-DEF.NON-NEUT	can	you	throw. away

'You can throw away this old newspaper'

Cross-linguistic variation is also found as to the number of articles and their morphological properties. So, for example, in several varieties of Danish, Frisian, and German, there are two definite articles, one of which is primarily anaphoric (Schroeder, 2005, and references therein).

As previously stated, definite articles may become void of their original deictic meaning in the course of time, but may also be able to mark other grammatical features such as gender and number. In spoken French, such development has led to a situation whereby articles often are the sole carriers of the number distinction, as exemplified in example (4):

(4)	written French	pierre	la pierre	les pierres
	spoken French	[pjɛʁ]	[la pjɛʁ]	[le pjɛʁ]
		'stone'	'the stone'	'the stones'

Indefinite Articles

In the preceding section, indefinite articles were characterized as being the grammatical elements that encode the identifiability of a referent in a noun phrase as not necessarily identifiable for the interlocutor. In the same way that definite articles can develop into specific markers, indefinite noun phrases are commonly analyzed in terms of their specificity. In this context, specificity concerns whether a specific individual or a specific group of individuals can be pointed out as the referent of a noun phrase by any participant within the current verbal exchange.

In languages worldwide, the numeral 'one' is the most common source of indefinite articles (Heine *et al.*, 2002), but indefinite pronouns may also develop into articles. According to Heine (1997: 72–76; see also Givón, 1981), the grammaticalization cline from the numeral 'one' to an indefinite article generally goes through the following stages, briefly characterized within parentheses:

Stage I: The numeral
Stage II: The presentative marker (Introduction of main participants)
Stage III: The specific marker (Singular nouns, specific to speaker)
Stage IV: The nonspecific marker (Singular nouns, nonspecific to speaker)
Stage V: The generalized article (Basically all nouns, including mass and plural nouns)

Most languages do not have an indefinite article (Dryer, 2005a), but almost all languages have numerals. Hence, many languages position themselves at the first stage in the cline. Once again, the decisive increase in frequencies of occurrence between the different stages may lead to the grammaticalization of an article, with the accompanying reduction in form (English *a*/∼/*an* < *one*) and the weakening of the original numeral meaning of the element. The cross-linguistic variation found in the use of the indefinite articles goes along the same lines as that for definite articles, i.e., there are examples of articles at different stages of development.

Whereas the English indefinite *a*/*an* is at stage IV, some languages have minified the numeral meaning of the article and it can be used with plural referents. This is the case, for example, in the Ibero-Romance languages, as seen in the following Spanish example:

(5a)	un-a	mujer
	INDEF-FEM	woman
	'a woman'	
(5b)	un-a-s	mujer-es
	INDEF-FEM-PL	woman-PL
	'some women'	

As is obvious from example (5), English must use *some* in this context. Hawkins (1991) has proposed that a phonetically reduced form *sm* indeed is an indefinite article in English, used with plural and mass nouns (much in the same way, thus, as the French partitive article).

Geographic Distribution

With regard to the absence or presence of grammaticalized articles, languages worldwide can be classified into four major types:

1. Languages without articles.
2. Languages with both DEF and INDEF articles.
3. Languages with only DEF articles.
4. Languages with only INDEF articles.

Languages without articles are found everywhere, but articles occur least frequently in the languages of Asia, South America, and the northern and eastern parts of North America. If a language has articles, it is

cross-linguistically more common to only a definite article, rather than both definite and indefinite articles; it is least common to have only an indefinite article (see Dryer, 2006). Languages with both DEF and INDEF articles are particularly common in Western Europe, in Meso-America, in the Pacific, and in a wide coast-to-coast belt across central parts of Africa. No particular tendencies as to geographical distribution can be found for languages of types 3 and 4 (having only one type of article, see Dryer (in press a,b)).

Concluding Remarks

As an effect of the gradual process of grammaticalization, the synchronic study of languages reveals great variation in the use of articles both between languages and within a language. An important parameter of this variation is degree of obligatoriness. Articles develop out of optional elements that undergo a dramatic increase in frequency as they gradually become obligatory, and are eventually totally predictable in certain contexts of use. For reasons of comparability, it is important to acknowledge the difference between optional and obligatory elements, or, grammaticalizing and grammaticalized constructions.

Artificial Languages

P O Bartlett, Vienna, VA, USA

© 2006 Elsevier Ltd. All rights reserved.

An artificial language is a language that has been deliberately designed for a purpose by one person or a small group of people over a relatively short period of time. (Adapted with permission from a definition by Richard K. Harrison, personal communication, 2004.) This definition, while serviceable, does lead to uncertain cases, such as whether pidgins should be considered artificial, being developed by small groups for a purpose, but usually pidgins are not considered to be artificial languages and will not be treated as such within the scope of this article. There is additionally the question of whether reduced languages such as Basic English (1930) are artificial. Also, this article pertains only to languages for interhuman communication and therefore does not address such constructs as computer programming languages.

Constructors can operate from any of several motives for designing a language. Some language designers intend that eventually their languages will replace an entire family of languages, such as Tutonish (1902) for the Germanic languages, or Ro (1906) for the entire world, considering that their languages would confer some overwhelming advantage to warrant replacing other existing languages.

Perhaps the most common design goal of artificial languages is international auxiliary languages, languages intended for use among people who do not have (or do not choose to use) any other language in common. Auxiliary languages, of which the best known but by no means the only is Esperanto (1887), may be intended to serve among localized areas (e.g., Guosa in Nigeria, 1965) or for the whole world. (Some have questioned whether replacement and auxiliary languages should be considered real languages. The experience of Esperanto, among others, tends to show that at least some such languages are adequate for any level of discourse for which their users want to employ them. Also, there are individuals who have learned Esperanto from infancy in Esperanto-speaking homes. Therefore at least some auxiliary languages are real languages.)

There are authors who have designed languages, at highly varying levels of specification and completeness, for artistic use or to be part of a fictional or mythic world. Examples are the Elvish languages of J. R. R. Tolkien's Middle Earth and Klingon on the *Star Trek* series.

A few languages have been designed to test some or other linguistic hypothesis. The original motivation of James Cooke Brown's Loglan (1960) seems to have been to test the Sapir-Whorf Hypothesis.

From time to time, smaller or larger groups have constructed languages in order to communicate among themselves without their communications being readily intelligible to outsiders. Often such concealment languages, such as the Pig Latin of childhood, are modifications of existing languages.

Special communication needs are a sixth motivation for constructing languages. Some, such as a later adaptation of Blissymbolics (originally Semantography, 1949), are designed for communication needs of persons with physical and/or mental disabilities. Languages allegedly usable in psychoanalysis and psychotherapy, such as aUI (1962), are another venue. Additionally, intended communication, at least on a rudimentary level, with hypothesized extraterrestrial beings can give rise to a language.

Some individuals (and occasionally small groups) construct languages merely for enjoyment, as hobbies, just as some people construct model ships.

Finally, there may be miscellaneous occasions, such as altered religious and/or mental states, although one might question whether some such languages are constructed for a conscious purpose.

Artificial languages, and auxiliary languages especially, have various provenances. The Indo-European (IE) matrix of language designers seems to be the most common provenance of languages readily documented, that is, the designers themselves tend to be speakers of IE languages, and the products are heavily influenced by an IE substrate. In many instances, the languages have an intended primary audience of speakers of European languages, including speakers of non-IE European languages. However, some languages such as Afrihili (1970) have target audiences other than Indo-European speakers (although the languages themselves are often presented and described using an IE language). On the other hand, some auxiliary languages may have an IE base but have an intended audience worldwide.

The history of artificial languages, even in the West, is extensive, and only the briefest outline is possible, inasmuch as the number of auxiliary languages alone is in the hundreds spanning several centuries.

One of the earliest constructed languages in the West of which there is a record is the Lingua Ignota of St. Hildegard of Bingen (12th century). It comprised a 23-letter alphabet and about 1000 words. It is not entirely clear whether she intended it as an amusement, as an auxiliary language, or

to express certain religious assertions, such as mystical states.

In the 13th–14th centuries, Ramón Llull wrote his *Ars Magna*, which he conceived as a perfect and universal language, especially for the religious conversion of non-Christians.

It was during the 17th century (and later) that the so-called *a priori* philosophical languages came to the fore, especially with the Real Character (1668) of Bishop John Wilkins in Great Britain. Perhaps the most notable characteristic of the philosophical languages is their basis in a classificatory scheme of (supposedly) all knowledge. Knowledge is broken into categories, and the vocabulary follows in almost mathematically combinatorial form from the classification.

During the 18th and 19th centuries, a number of artificial language proposals surfaced, such as the rather eccentric Solresol (1827) by (Jean) François Sudre, based on a seven-note musical scale, which did, nonetheless, gather some interest.

Volapük, invented in 1879 by the Catholic priest Johann Martin Schleyer, was the first artificial language designed as an auxiliary language to gain any substantial following. It was an *a posteriori* language, i.e., one in which the grammar and (especially) vocabulary derive from one or more existing languages, although word forms of Volapük were greatly modified from readily recognizable forms. The language enjoyed considerable initial enthusiasm throughout Europe and North America, although that enthusiasm quickly waned due to what some considered to be shortcomings in the language itself, factional infighting within the movement, and the rise of Esperanto. (There were, however, some derivatives of Volapük itself, and the language, in a revised form, did have some slight revival in the 20th century.)

Esperanto (1887), the brainchild of Ludwig Lazarus Zamenhof (spellings vary), has become the most successful, in relative terms, of all the artificial auxiliary languages to date. It has a largely Indo-European grammar with a rather agglutinative word-formation system. Estimates of the number of Esperanto speakers differ widely and are controversial, ranging from a few tens of thousands to several million. Over the decades, people have raised various objections to Esperanto's structure, vocabulary, or orthography (which includes some accented letters unique to itself). Consequently, Esperanto has given rise to numerous derivatives, of which the only one to have any significant number of users at all has been Ido (1907).

Several artificial languages have the design goal of being naturalistic in terms of recognizability to speakers of west European languages. Notable among them have been Latino sine Flexione (1903) by Giuseppe Peano, a kind of Latin with most of the inflections stripped out, Occidental (1922) of Edgar de Wahl, and Interlingua (1951) of the International Auxiliary Language Association, Inc.

A few artificial languages have been known as logical languages, being based on predicate logic rather than on more common grammatical principles. Among these are Loglan (1960) and Lojban (1988) by the Logical Language Group, Inc.

Finally, there have been numerous artificial languages, too many and too varied to try to describe here even cursorily, that might be subsumed under the catch-all heading of just about anything under the sun. They have characteristics similar to those of languages all over the world.

Artificial languages have various features in both grammar and vocabulary, although the grammars of auxiliary languages (at least those developed by Westerners) often (although not always) tend to follow an Indo-European model.

A priori languages, first mentioned above, have two overlapping types. There are those, such as Wilkins's Real Character, Foster's Ro, or Elam's Oz (1932), which follow a classificatory system for vocabulary, as noted above. Such schemata are open to several criticisms:

- The totality of knowledge does not always fit neatly into a simple and single taxonomic schema.
- The taxonomic schema is dependent on the state of knowledge at the time of the creation of the schema.
- It can be difficult to fit new discoveries, taxa, and techniques into the schema, as the schema tends to be relatively closed.
- In practice there is a prodigious demand on the memory (and on the oral-aural channel) to retain the schema and to make fine distinctions (both semantic and oral).

Another use, however, of the term '*a priori*' is simply a reference to artificial languages whose vocabularies are made up *ad hoc* and not derived from the vocabularies of existing languages. Some languages of this type (many examples could be cited) may have some internal structure to the vocabulary, primarily for mnemonic value, but do not follow a classificatory scheme as such.

A posteriori languages have their grammar and vocabulary bases in existing languages. The degree to which the vocabulary items are deformed varies widely.

There are also logical languages, as mentioned above. Their vocabulary may be *a priori* or at least partially *a posteriori*.

Auxiliary languages in particular can have different intended audiences and purposes. Some designers target their products largely for informal, personal use, such as among travelers and correspondents. On a wider scale, commercial and professional applications may come into purview. IALA Interlingua has seen some professional use in the past, but few languages seem to have yet found much widespread use in the commercial realm. Intergovernmental use, such as diplomacy and treaties, may be encompassed within the design of a language, although none have yet made significant inroads into this area. Different members of target audiences may have different assessments of the ease with which adult learners can acquire and use an artificial language.

Artificial languages in general (and not just auxiliary languages) differ markedly in their division of semantic space. Some have a rich vocabulary, making fine semantic distinctions, and others have a much more restricted vocabulary, depending on periphrasis to convey distinctions. Languages differ widely in how they handle (or even allow) unassimilated or partly assimilated foreign terms.

The issue of idiom often tends not to be treated extensively in the construction of auxiliary (and other artificial) languages. As a result, many users often import native idioms, impeding ready communication, or make conscious efforts to avoid idiom entirely. Of course, there is nothing to prevent a body of users from developing over time idioms unique to the user base itself.

Just why an auxiliary language does or does not have much use (in terms of speaker base) may depend on several factors. Not all of these factors are linguistic characteristics in and of themselves. Among them are:

- Propitiousness of circumstances, or 'right place at the right time.' In some language milieux, there is simply little felt need for an auxiliary language.
- Perception by prospective learners and users that the language itself is adequate for the task and sufficiently easily acquired by adult learners. This factor, although highly subjective, is operative. This factor can be called 'good enough.'
- A proposed international auxiliary language must have a stable enough base so that it is not always moving under the feet, so to speak, of would-be users. (Some language designers continue indefinitely to make changes.)
- A language proposal must be sufficiently dispersed to the attention of prospective users, with didactic material available.
- Proponents must have sufficient enthusiasm to work against social inertia.
- Proponents must have at least a minimally sufficient organization at some time to assist propagation.
- External events, such as wars or government favorable (or disfavorable) attention, may work for or against the spread of an auxiliary language.

Although much material exists for individual artificial languages, there are few comprehensive studies of artificial languages in general. Most available material relates to international auxiliary languages, and some of that is on a popular level. Some of the works cited in the Bibliography contain further references for the interested reader.

Aruba: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Aruba has been autonomous from the Netherlands Antilles since 1986 but remains part of the Kingdom of the Netherlands. Dutch is the official language, with 94 000, mostly second-language, speakers. The language situation in Aruba falls together with those in Bonaire, Curaçao, and the Netherlands Antilles. In Aruba, by far the most common language spoken in the home is Papiamentu (77%), followed by English (9%), Spanish (7%), and Dutch (5%). Papiamentu is an Iberian-based creole with 70 000 speakers in Aruba. It is also known as Papiam, Papiamento(e), Papiamen, Curaçoleño, and Curassese.

Papiamentu developed as a contact language used in the Dutch slave trade. Since the Dutch developed their trading routes and colonies in competition with, and frequently at the expense of, the Portuguese and Spanish, an Iberian-based contact language was used. A minority which played a significant role in the development of Papiamentu were Portuguese-speaking Sephardic Jews, who were persecuted by the Portuguese and consequently tended to settle in Dutch colonies. In Curaçao, about half the European population were Sephardic Jews. The oldest extant Papiamentu document is a letter written by a Curaçao Jew in 1776. Papiamentu reached Aruba by the end of the 18th century.

Nowadays, Papiamentu has considerable prestige in Aruba and seems to be approximating gradually to Spanish, which is a prestige language. This is apparently more pronounced in Aruba than in Curaçao. Papiamentu is taught during the first two years of primary school and has a published grammar, dictionary, and, since 1997, a translation of the Bible. The first newspaper texts printed in Papiamentu date from 1871, indicating that the language was widely accepted from an early stage. It is also the primary language in the informal sector, social life, and some political debate. The current debate around the status of Papiamentu reflects its increasing role as a language of national identity, although some separatist suggestions of a partitioning of the country could result in the formation of two different standardized varieties. Probable factors that have influenced the acceptance and standardization of Papiamentu include multilingualism, high literacy rates, and a high standard of living combined with ethnic leveling through intermarriage.

Despite, or perhaps because of, the widespread use of Papiamentu, there exist sociolects which are associated with prestige. In addition, the inability to use Dutch still hinders social and political mobility. Dutch is the language of jurisdiction and is dominant in the political, cultural, and economic spheres. Dutch and English are both taught in high school and are used with tourists, although Spanish is widely used with Spanish speakers.

Ascham, Roger (1515–1568)

W Viereck, Universität Bamberg, Bamberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Roger Ascham [‘Askəm] was born in Kirby Wiske, Yorkshire, England in 1515 or 1516. He began his studies at St. John’s College in Cambridge, England in 1530, and was eventually appointed as university orator and tutor for the children of King Henry VIII, notably Mary and Elizabeth. Ascham obtained a B.A. degree in 1534 and an M.A. degree in 1537. Ascham began lecturing in Greek at St. John’s, but resigned his position due to ill health. In 1545 he published *Toxophilus: the schole of shootinge,* an essay on the English longbow, and dedicated it to King Henry VIII, an ardent archer, who subsequently awarded Ascham an annual pension for this work.

In 1550, as secretary to the English ambassador to Emperor Charles V, Ascham visited Continental courts and some of the scholars with whom he had corresponded, such as the reformers Philip Melanchthon and Johannes Sturm, who helped shape European classical education. Ascham returned to Cambridge in 1553, and accepted the position of Latin secretary to Queen Mary, even though he had Protestant leanings. After her sister’s death in 1558, Queen Elizabeth appointed Ascham as a prebendary at York. The position gave him the financial security to embark on his major work that is especially noteworthy in the history of education, as it was one of the first educational treatises in Europe written in the vernacular, and is known as *The Scholemaster*: *or plaine and perfite way of teachyng children the Latin tong*. He could not complete it due to illness, and his wife had it published two years after his death.

Ascham’s employment of the vernacular contributed much to its prestige. In *Toxophilus,* he expressed the hope that an English book would be “a thinge Honeste for me to write, pleasaunt for some to rede, and profitable for manie to follow.” Ascham’s use of the vernacular is no evidence that he admired it. In *The Scholemaster,* he wrote “next to the Greeke and Latin tong, I like and loue [Italian] aboue all others.” The study of classical literature was for him a fundamental principle necessary for a liberal education, and the study and use of Latin was very important for developing elegance of expression in the English language. Ascham used the method of ‘double translation’ (from Latin into English, and then from the English version into the Latin original) in teaching foreign languages. Ascham is credited with the ‘double translation’ invention. However, this method had been advocated long before him in bilingual collections of vernacular syntagms followed by their Latin counterparts; see Foster Watson, 1908.

Ascoli, Graziadio Isaia (1829–1907)

W H Veith, Univeristät Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Ascoli (Figure 1) was born into a Jewish family in North Italian (Friaulian) Gorizia (*Görz* while belonging to Austria), today at the border with Slovenia. Consequently, the child Ascoli was confronted with several language systems. Ascoli did not need to attend public schools. He studied so immensely that—at the age of 16—he had the intellectual level to publish an essay on the affinity of Furlanic (Rhaeto-Romanic) and Valacan by Walachian (Rumanian). When he was 25, he began to publish books, first on Oriental languages. At the age of 32, in 1861, he accepted a chair for Comparative history of classical and neo-Latin languages at Milan University.

Ascoli was the founder of Romance studies in Italy. At first, however, he concentrated on Hebrew, Sanskrit and classical languages. Two descriptions of contemporary Romance languages were sensational: (1) on Ladin in 1873, (2) on Franco-Provençal,

Figure 1 G. I. Ascoli. Photo from *AGI XX* (Sezione Neolatina 1926).

isolated and introduced as a term by Ascoli in 1878, which caused a polemic discussion with French linguists. In 1873, Ascoli founded the periodical *Archivio glottologico italiano* ('Archive on Italian language studies') essentially to offer monographs, articles and reviews on Italian dialects, their systematization in comparison with neighboring dialects and Latin as a reference. Some of Ascoli's publications also were a linguistic answer to the position of the novelist Manzoni in the 'questione della lingua.' He edited the *AGI* until 1901 and delivered numerous contributions (Terracini, 1923), as well as studies on the Irish and Celtic languages. These were the major fields of his last activities.

In his comparative studies, Ascoli assumed a structural similarity between Indo-European and Non-Indo-European, e.g., Semitic (cf. D'Ovidio, 1910). Ascoli's foresight, at that time met with opposition, was confirmed, e.g., by the Danish linguist Holger Pedersen and later independently by the nostratic theory. This view and also his preference for living languages over describing dead ones were arguments, besides others, against the Neogrammarians.

Ascoli explained many exceptions of today's Italian dialects by a supposed pre-Latin, e.g., Gallic, substratum. The term 'substratum' had been used since 1821 (cf. Francescato, 1970: 12) and meant 'underlying original language,' but it was Ascoli who brought the substratum theory to the attention of the contemporary linguists. The substantial linguistic terminology developed by him (cf. De Felice, 1954) reflects his various theoretical and methodological approaches to language and historical linguistics. In his opinion, linguistic change is considered under four aspects (cf. Tagliavini, 1998: 102): the ethnic influence, the chorographic (i.e., geographic) situation plus the inner congruence (i.e., the identity with the underlying substratum) and the outer congruence (i.e., the same linguistic change also appears in nonrelated systems).

Asher, Ronald E. (b. 1926)

E K Brown, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

Ron Asher was Editor-in-Chief of the first edition of *The Encyclopedia of Language and Linguistics* (ELL1) (1994).

He was educated at King Edward VI Grammar School, Retford, Nottinghamshire, and at University College London, where in 1950 he gained a B.A. in French. He stayed on at UCL as an assistant in the French Department and to work for a Ph.D. in Renaissance French. This was awarded in 1955, and a revised version of his thesis was eventually published in 1993 as *National myths in Renaissance France: Francus, Samothes and the Druids*. During the time that he was a graduate student at UCL, anxious to improve his spoken French, he studied for the UCL Certificate in the Phonetics of French, thus laying a firm practical and empirical foundation for the linguistic fieldwork he was soon to take up and starting a lifelong interest in phonetics and phonology that culminated in *Towards a history of phonetics* (1981), which he jointly edited with Eugénie Henderson.

In 1953 he took up a post in the School of Oriental and African Studies. It was intended that after a period of training in linguistic theory and the linguistic description of Dravidian languages, and practical courses on Tamil language in the Department of Phonetics and Linguistics, he would take up a lectureship in Linguistics and Tamil in the Department of India, Pakistan and Ceylon. At that time the Professor of Linguistics in SOAS was J. R. Firth, whose views on language had a profound influence on Ron Asher's attitude toward language and linguistics and the relation between them – an influence that was in time to be reflected in ELL1. He has written of his time in Firth's department:

> What immediately appealed to me... was that, no matter how abstract the theorising, there must always be the possibility of 'renewal of connection with experience' of actual language use. A strong impression left with me from my conversations with Firth and from listening to his lectures was that he did not see linguistic theory and the description of languages as belonging to two separate domains, with work in one being able to proceed in isolation from the other; good descriptive work is possible only in the context of a sound theoretical approach, and theorising is empty without some reference to descriptive material. (Asher, 2002: 31).

In the 1950s, staff members at SOAS were provided with a language informant and were expected to take regular periods of study leave in the country in which their language was spoken. From his first informant at SOAS, Asher soon discovered that the modern written Tamil that he was being taught in class was very different from everyday spoken Tamil. This practical encounter with Tamil diglossia was reinforced by his visits to South India. On these visits, because his department taught both language and literature, he divided his time between the study of spoken Tamil and other Dravidian languages and the study of Tamil literature, both classical and modern. The study of Dravidian languages resulted in later years in descriptive grammars of Tamil (Asher, 1992; Asher and Annamalai, 2002) and Malayalam (Asher and Kumari, 1997). The study of Tamil literature led to a collection of Tamil prose made in collaboration with his SOAS informant (Asher and Radhakrishnan, 1971) and a lifetime friendship with two of Kerala's most prominent novelists, Thakazhi Sivasankara Pillai (1912–2000) and Vaikom Muhammed Basheer (1908–1994), whose works he has translated (Basheer, 1980; Pillai, 1993).

In 1965 he left SOAS for a post in John Lyons's newly established Department of General Linguistics in Edinburgh. In due course, in addition to his academic teaching and publishing he became successively Dean of the Faculty of Arts and Vice-Principal of the university. And it was in Edinburgh, in 1988, that his wide range of interests in linguistics, languages, and literature led to an invitation by Alan Steele of Pergamon Press and Angus McIntosh, then Professor of English Language at Edinburgh, to join in discussions that led to his appointment as Editor-in-Chief of ELL1. His vision for ELL1 was

> ... that the Pergamon encyclopædia should seek to display four characteristics: it should be authoritative, international in authorship and content, comprehensive, and up-to-date.... A further characteristic of the work was that it should aim to be informative rather than polemical or sectarian. It should as far as possible provide information on any subject that might seem relevant to a person interested in any aspect of the serious study of human language. It was this that motivated the decision to have as its title *The Encyclopedia of Language and Linguistics* (*ELL*) (Asher, 2002: 38).

Alphabetic writing, regardless of the degree to which vowels are represented graphically, is animated by the principle of having one grapheme per sound (an ideal only) and makes use of syllabaries (sign-lists) comprising signs numbering only in the tens instead of the hundreds more typical of logographic, syllabic, and logosyllabic writing systems. The origins of this form of writing date to the very beginning of the second millennium B.C.E. and are evidenced in two main script traditions. The first, and earlier of the two, is drawn in lines (originally pictographic or semipictographic) and is strongly indebted to Egyptian models of writing – indeed, it now appears that Egypt proper is the likeliest place for the invention of this script type. And it is this linear form of alphabetic writing that is eventually borrowed by the Greeks (from the Phoenicians) and transmitted throughout the world. The second script tradition dates from a slightly later period (ca. 14th century B.C.E.) and are currently attested mainly from the ancient north Syrian kingdom of Ugarit and its environs. This form of alphabetic writing employs wedge-shaped cuneiform signs (typically impressed with a stylus on wet clay) inspired by the writing system of the other dominant ancient Near Eastern civilization, Mesopotamia. Unlike the linear tradition, however, alphabetic cuneiform did not survive the great civilization collapse that swept across the Levant at the end of the Late Bronze Age. The early histories of these alphabetic forms of writing are recounted here.

Serabit el-Khadem

The modern study of alphabetic origins dates to 1905 and the discovery of a sanctuary at Serabit el-Khadem and related turquoise mines in a remote part of southern Sinai. The sanctuary dates to the Egyptian Twelfth Dynasty (ca. 1991–1785 B.C.E.) and mining operations were active in the area from that time through the New Kingdom period. In addition to the large number of Egyptian inscriptions, excavations at the sanctuary and the surrounding mines yielded a score or so of very short and poorly preserved inscriptions in what at that time was an unknown script (**Figures 1–2**). The script employs a limited number of signs (between 20 and 30 in all), which are pictographic (or semipictographic) and bear a strong resemblance to corresponding Egyptian forms, both hieroglyphic and hieratic (see esp. Hamilton, 1985), though the language itself is not

And it is this linear form of alphabetic writing that is eventually borrowed by the Greeks (from the Phoenicians) and transmitted throughout the world. The second script tradition dates from a slightly later period (ca. 14th century B.C.E.) and are currently attested mainly from the ancient north Syrian kingdom of Ugarit and its environs. This form of alphabetic writing employs wedge-shaped cuneiform signs (typically impressed with a stylus on wet clay) inspired by the writing system of the other dominant ancient Near Eastern civilization, Mesopotamia. Unlike the linear tradition, however, alphabetic cuneiform did not survive the great civilization collapse that swept across the Levant at the end of the Late Bronze Age. The early histories of these alphabetic forms of writing are recounted here.

Serabit el-Khadem

The modern study of alphabetic origins dates to 1905 and the discovery of a sanctuary at Serabit el-Khadem and related turquoise mines in a remote part of southern Sinai. The sanctuary dates to the Egyptian Twelfth Dynasty (ca. 1991–1785 B.C.E.) and mining operations were active in the area from that time through the New Kingdom period. In addition to the large number of Egyptian inscriptions, excavations at the sanctuary and the surrounding mines yielded a score or so of very short and poorly preserved inscriptions in what at that time was an unknown script (Figures 1–2). The script employs a limited number of signs (between 20 and 30 in all), which are pictographic (or semipictographic) and bear a strong resemblance to corresponding Egyptian forms, both hieroglyphic and hieratic (see esp. Hamilton, 1985), though the language itself is not

Figure 1 Sinai 349.

Figure 2 Sinai 363.

Figure 3 Sinai 346.

Figure 4 Sphinx and Sinai 345 (facing view).

Egyptian. W. M. F. Petrie, the original excavator, guessed the alphabetic nature of the new script (1906: 130–131), but it was the work of A. H. Gardiner (1916), and, in particular, his successful decipherment of one of the recurring sequences of signs in these texts (house-eye-shepherd's crook-mark [=*b'lt*] 'Baalat' or 'Lady', a Semitic epithet apparently applied to the Egyptian goddess Hathor, see Figure 3) that securely established the thesis. Gardiner's breakthrough was based on his recognition that in addition to the signs' often close graphic similarities to comparable Egyptian shapes, some of them also resembled the form of letters from the later linear Phoenician alphabetic script. From this he deduced their alphabetic quality and hypothesized that the language of the inscriptions was likely West Semitic – presumably the people who left these inscriptions were Asiatics in the employ of the pharaohs (or enslaved by them).

The underlying principle informing this new script is acrophony, a principle by which the picture iconically depicted by a sign represents not the word for the thing portrayed but the initial (consonantal) sound of that word (e.g., the picture of an ox head represents the letter *'aleph*, the initial letter in the Semitic word *'alpu* 'ox'). Scholars had long supposed that the traditional names for individual letters in the various later alphabetic traditions were likely very old. Gardiner's estimation of acrophony as the generative force in the development of the new alphabetic script strongly suggests that this in fact is the case and, what is more, that the letter names themselves furnish important data for reconstructing the original consonantal values of the individual signs.

The long-time consensus of an Eighteenth Dynasty date (ca. 1500 B.C.E.) for the Proto-Sinaitic inscriptions, as these texts have become called, now seems less tenable. With little in the way of positive indication (aside from the inscriptions themselves) for any date in evidence at the site, scholars, especially W. F. Albright (1963), had seized upon the presumed date of the little sphinx bearing an alphabetic inscription (Sinai 345; see Figure 4) attributed to the time of Hajeptsut (see esp. Leibovitch, 1963) as the surest indicator of the age of these texts. However, Egyptologists now agree that the sphinx in question likely comes from the Middle Kingdom period, the same period originally favored by Gardiner for these inscriptions' time of origin. More recent paleographic analyses of the corpus also point to the Middle Kingdom as the likeliest period of origin for these inscriptions (Sass, 1988: 139, 142–144; Hamilton, 2002: 40, forthcoming), as do the recently recovered early alphabetic texts from the Wadi el-Hol.

The Wadi el-Hol Early Alphabetic Texts

The newest additions to the early alphabetic corpus are two short, complete inscriptions from the Wadi el-Hol (Figures 5–6), a site located at the midpoint of the main Theban road into the Western Desert. The rock face of the great wadi cliffs that make up the site is covered with hundreds of Egyptian inscriptions and drawings, the large majority of which come from the Middle Kingdom period. It was in the process of drawing, recording, and photographing these Egyptian inscriptions that J. C. and D. Darnell came across the two early alphabetic texts that they described as being "written in the Proto-Sinaitic script" (Darnell and Darnell, 1997: 46–47). Like much of the Serabit el-Khadem corpus, these two inscriptions have so far defied satisfactory decipherment. Still, their alphabetic character is apparent – they are not decipherable as any form of Egyptian; they employ a radically abbreviated number of graphemes; and most of the individual signs bear very close resemblance to or exhibit clear continuity with the various signs as known from the emergent alphabetic script traditions (e.g., ox head → *'alep*, seated figure → *he*, house → *bêt*). And as with the Serabit el-Khadem inscriptions, the writing is oriented variously (one horizontally, the other vertically) with individual signs facing both left and right.

Though these newly recovered inscriptions require broader scrutiny, their significance for understanding the early history of alphabetic writing can already be estimated. First, it is much more obvious from the Wadi el-Hol inscriptions (given the striking closeness in appearance of many of the letter forms to Egyptian

Figure 5 Wadi el-Hol 1 (horizontal).

Figure 6 Wadi el-Hol 2 (vertical).

signs) that alphabetic writing is a derived script tradition. That is, the forms of the earliest alphabetic signs were borrowed from a "pre-existent and often developed range of shapes in their Egyptian prototypes" (Hamilton, 2002: 39), prototypes that included both hieroglyphic *and* hieratic forms. Though already apparent from the Serabit el-Khadem corpus (see esp. Hamilton, 1985), the mixed character of Egyptian prototypes used for alphabetic forms is prominent in the two Wadi el-Hol graffiti as well. Second, through paleography and contextual considerations, the Wadi el-Hol texts may be dated far more confidently than those from Serabit el-Khadem, thus providing a more stable anchor from which to assay the chronology of early alphabetic writing. Paleographically, the letter forms derived from hieratic models are all important, since hieratic evinces diachronic variation and thus is tractable chronologically in ways not possible for Egyptian hieroglyphs. In particular, the specific paleographic models used for certain of the hieratically derived signs (e.g., the head, serpent, seated figure signs), the mixed use of both hieratic and hieroglyphic models, and the vertical orientation of otherwise predominantly horizontally oriented signs (especially the two water signs) indicate an emerging paleographic profile for these signs that fits most naturally within a Middle Kingdom milieu. Contextual considerations – the prominent location of the alphabetic inscriptions on superior rock surface and in the midst of hundreds of late Middle Kingdom and Second Intermediate Period Egyptian inscriptions, the so-called Bebi inscription, which places Asiatics at the Wadi el-Hol precisely during the late Middle Kingdom – point more precisely to the later Middle Kingdom (late Twelfth to early Thirteenth Dynasty, ca. 1850–1700 B.C.E.) as the likeliest time of inscription for these texts, and thus a date early in the Egyptian Middle Kingdom (early to mid-Twelfth Dynasty, ca. 1900 B.C.E.) cannot be far off for the beginning of alphabetic writing. Third, the likelihood that alphabetic writing began geographically in Egypt proper is now, with the recovery of alphabetic writing from the heart of the Western Desert, a thesis deserving serious consideration. Lastly, the Wadi el-Hol texts contribute to a clearer understanding of the development of certain individual alphabetic letter forms, add to the list of alphabetic signs with known biforms, and attest several previously unknown signs.

Early Alphabetic Writing from the Levant

Apart from the Serabit el-Khadem texts and the two rock-cut graffiti from the Wadi el-Hol, the remainder of the early alphabetic corpus comes from the southern Levant. This corpus is comparable in size to that of Serabit el-Khadem, numbering between 20 and 30 epigraphs (depending on what is included; see Hamilton, 1985, forthcoming; Puech, 1986; Sass, 1988) and forms a single continuous script tradition with the early alphabetic texts from Egypt and Sinai. These inscriptions, too, are mostly short, fragmentary, and enigmatic. They divide into two unequal groups. The smaller group contains the earliest inscriptions, all dating roughly to the end of the Middle Bronze Age (ca. 1650–1500 B.C.E.), and at minimum would include the Najila sherd, Lachish dagger, and Gezer sherd. Sometimes labeled Proto-Canaanite (Hamilton, 1985: 3), the scripts of these inscriptions, like those of the texts from Serabit el-Khadem and the Wadi el-Hol, remain (more or less) transparently pictographic, even when the letter forms are derived from the more schematized and abbreviated hieratic shapes. In the second, and larger, group, sometimes referred to as Old Canaanite (Hamilton, 1985: 3), various of the letter forms are beginning to lose their

Figure 7 Shechem plaque.

Figure 8 Grossman seal.

Figure 9 Abecedary from Izbet Sartah.

Figure 10 Inscribed bronze arrowheads from the 11th century B.C.E.

recognizably pictographic shape and the script tradition as a whole is becoming more linear. This process is already setting in by around 1400 B.C.E. (e.g., the Shechem plaque and the Grossman seal; see Figures 7 and 8) and is well advanced by the end of the 13th and beginning of the 12th centuries, as evidenced, for example, by the Izbet Sartah ostracon (ca. 1200 B.C.E.; Figure 9), the longest of the early alphabetic inscriptions so far recovered. The 11th century marks the end of the use of pictographic letter forms and the advent of the fully linear alphabetic script tradition. The collection of more than 30 inscribed bronze arrowheads from the period (see Cross, 2003: 200–202 for a convenient tabulation) provides an exquisite witness to this important transitional period. In the earliest of these arrowheads (e.g., El Hadr I–III in Figure 10), some pictographic forms are retained, letter stance is still variable, and vertical writing is permitted. But by the end of the century all has changed. Pictographic forms die out completely, the direction of writing (sinistrograde, from right to left) becomes standardized, and letter stances are fixed. The latest in the sequence, that of Azarbaal son of Adonibaal (no. 7 [Beirut Museum], Milik, 1961), dates into the 10th century, and thus overlaps with the earliest linear Phoenician inscriptions (e.g., Ahiram [KAI 1], ca. 975 B.C.E.). And thus, with the turn of the millennium, a new phase in the history of (linear) alphabetic writing begins.

Alphabetic Cuneiform

One consequence of the delinguistic character of writing, observes M. O'Connor (1983: 441), is that "it is at least as likely for **the notion** of a writing system to be borrowed as for **the system itself** to be taken over." The paradigm example from antiquity is the invention of alphabetic cuneiform in the 14th century (Figure 11). The place of invention cannot be known for certain but there is no reason not to think that it was in the ancient kingdom of Ugarit on the north Syrian coast. Since 1929 some 1500 cuneiform tablets in an alphabetic script have been recovered from excavations at Ras Shamra and its immediate environs. The scribes of Ugarit, well schooled in the syllabic cuneiform writing system of Mesopotamia, borrowed the notion of cuneiform writing and its technique and created a syllabary of 30 signs to write the local Northwest Semitic dialect spoken at Ugarit. The individual signs themselves are composed of simple combinations of long, short, and/or angled wedges but they bear no paleographic resemblance to signs in syllabic cuneiform (see esp. Windfuhr, 1978). Neither are their shapes obviously influenced by the shapes of the early linear alphabetic pictographs (see e.g., Cross, 2003: 318; Millard, 1979: 615), even though Ugaritic alphabetic cuneiform shares a common heritage with the linear

Figure 11 Alphabetic Cuneiform (examples from Kirta).

Standard Ugaritic order: ʾbgḫdhwzḥṭykšlmḏnẓsʿpṣqrṯġtiuś

Standard Phoenician order: ʾbg dhwzḥṭyk lm n sʿpṣqrš t

Figure 12 Order of alphabetic signs.

alphabetic script tradition, as shown most tellingly by the order of the signs in abecedaries, which is the same in both script traditions (see **Figure 12**) and the shared tradition of letter names (Cross and Lambdin, 1960; Cross and Huehnergard, 2003). Indeed, the cuneiform alphabetic tablets from Ugarit are the earliest fully deciphered corpus of alphabetic writing yet discovered.

The script used to write alphabetic cuneiform actually is attested in two varieties. The longer version is the normal one used at Ugarit itself (**Figure 13**). Its 30 signs represent the 27 phonemes of the local Ugaritic dialect plus three supplemental signs (*ʾi*, *ʾu*, *ś̌*). The latter are placed at the end of the sign sequence in the standard abecedaries from Ugarit. The first two of these are *ʾaleph* signs; they join with the initial *ʾaleph* sign (which stands at the head of the abecedary) to represent the syllabic values /ʾa/, /ʾi/, and /ʾu/. The last sign (*ś̌*) is a rarely used biform of *s* that is generally limited to loanwords. Texts using this script are generally written from left to right (as with syllabic cuneiform). A shorter script, presumably corresponding to the 22-letter script better known from linear Phoenician and the first millennium West Semitic scripts, is discernible in a handful of tablets from Ras Shamra and Minet el-Beide (*CTU* 1.77; 4.31, 710; 7.60) (*The cuneiform alphabetic texts from Ugarit, Ras Ibn Hani, and other places*. Edited by M. Dietrich, O. Loretz, and J. Sanmartin, Münster, 1995 (the number identifies the specific text in the collection) and on tablets or inscribed objects found at sites outside of Ugarit, such as Tell Nebi Mend, Kamid el-Loz, Sarepta, Tell Taanak, and Mount Tabor. The direction of writing in texts using this script is generally from right to left, meaning the signs are the mirror image of the

Figure 13 Standard abecedary from Ugarit. *CTU* 5.6.

corresponding signs in the standard script. The two scripts are used contemporaneously and more or less in complimentary distribution. The authenticity of the longer form is not to be doubted, given its overwhelming prominence at Ugarit and the interspersing (instead of appending) of the five 'extra' graphemes in the standard Ugaritic abecedaries – indeed, a longer script of this type is presumed by the graphic (and phonemic) inventory of the extant early linear alphabetic inscriptions from Egypt and the southern Levant as well. Whether the shorter script, then, is derivative of the longer is harder to tell. Ugarit must be presumed to be the center of alphabetic cuneiform learning during the Late Bronze Age, and there the long script clearly prevails.

One of the most recent and surprising discoveries from the ongoing excavations at Ras Shamra-Ugarit is an abecedary (RS 88.2215) preserving the South Semitic order of alphabetic signs (i.e., *h-l-ḥ-m*, cf. Bordreuil and Pardee, 2001). Recent reanalysis of the long-known Beth Shemesh tablet (*CTU* 5.24) reveals that this tablet contains a similarly ordered abecedary (see esp. Loundine, 1987). These abecedaries (perhaps reflecting a language or languages other than Ugaritic) unambiguously show the antiquity of the South Semitic letter order and mean that it is increasingly likely that the Proto-Arabic script tradition branched off from the linear alphabetic script traditions relatively early (cf. Cross, 1954: 22, 1967: 19*). And further, they, along with the alphabetic cuneiform inscriptions originating outside of the environs of Ugarit proper, suggest that knowledge and use of alphabetic cuneiform may have been far more widespread in the Levant than previously thought.

Asia, Ancient Southwest: Scripts, Epigraphic West Semitic

C A Rollston, Emmanuel School of Religion, A Graduate Seminary, Johnson City, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

Two primary categories of linear scripts are evidenced for ancient Near Eastern alphabetic texts: lapidary and cursive (cf. Daniels, 1990, on the problems with the term 'alphabet'). The dominant features of a lapidary script are its graphic arrangement, letter clarity, uniformity of letter form and size, and general conservativeness (i.e., retarded development). Lapidary inscriptions are normally found on surfaces that were carefully prepared, and in general they were intended to be permanent. The primary features of a cursive script are the rapidity with which it can be written and its adaptability. For a cursive script, variations in letter form and size are common, stroke curvature tends to be more prominent, letter spacing is more compact, semiligatures are more common, and development occurs more rapidly. Writing instruments and media are of fundamental importance in this regard but not always determinative (because cursive scripts can be employed on stone). For the scripts that constitute the focus of this article, both lapidary and cursive traditions are attested. Drawings of various inscriptions, on various media (metal, pottery, and stone), with various writing instruments (chisel, incising tool, and brush and ink) are included so as to demonstrate some of the diversity of the epigraphic material in West Semitic scripts. Finally, it should be noted that paleography is the field that focuses on precise analysis of a script series, and stringent paleographic methods produce the most convincing

Asia, Ancient Southwest: Scripts, Epigraphic West Semitic

C A Rollston, Emmanuel School of Religion, A Graduate Seminary, Johnson City, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

Two primary categories of linear scripts are evidenced for ancient Near Eastern alphabetic texts: lapidary and cursive (cf. Daniels, 1990, on the problems with the term 'alphabet'). The dominant features of a lapidary script are its graphic arrangement, letter clarity, uniformity of letter form and size, and general conservativeness (i.e., retarded development). Lapidary inscriptions are normally found on surfaces that were carefully prepared, and in general they were intended to be permanent. The primary features of a cursive script are the rapidity with which it can be written and its adaptability. For a cursive script, variations in letter form and size are common, stroke curvature tends to be more prominent, letter spacing is more compact, semiligatures are more common, and development occurs more rapidly. Writing instruments and media are of fundamental importance in this regard but not always determinative (because cursive scripts can be employed on stone). For the scripts that constitute the focus of this article, both lapidary and cursive traditions are attested. Drawings of various inscriptions, on various media (metal, pottery, and stone), with various writing instruments (chisel, incising tool, and brush and ink) are included so as to demonstrate some of the diversity of the epigraphic material in West Semitic scripts. Finally, it should be noted that paleography is the field that focuses on precise analysis of a script series, and stringent paleographic methods produce the most convincing

assessments of the diachronic development and synchronic variation of a script series (Cross, 1982; Rollston, 2003).

The Phoenician Script

Alphabetic Semitic inscriptions are attested throughout much of the 2nd millennium (Albright, 1966; Sass, 1988). Many of these inscriptions are pictographic, but several thousand alphabetic cuneiform tablets have been discovered as well (Segert, 1984). Alphabetic cuneiform was ephemeral, but the pictographic alphabetic script ('early alphabetic,' following McCarter) continued to develop throughout the 2nd millennium B.C.E., becoming more linear with the passage of time (Cross, 1967). During the terminal horizons of the 2nd millennium, several developments are of fundamental importance: (1) The letters have become quite linear; (2) the stance has stabilized; (3) the direction of writing is consistently sinistrograde (rather than the sinistrograde, dextrograde, and boustrophedon of earlier periods); and (4) the alphabet consists of 22 letters, reflecting a number of 'consonant mergers' (rather than preserving the larger stock of Semitic consonants attested for the pictographic and cuneiform scripts). These features are present during the mid-11th century; this script is referred to as Phoenician.

Phoenician inscriptions have been discovered at numerous sites. The bronze spatula inscription (late 11th century or very early 10th century B.C.E.) was a 'prestige item' (in the shape of an arrowhead) from Byblos ('Gebal') (Figure 1). Six lines of Phoenician text (often considered enigmatic) are etched into the metal. There are numerous archaic features of this inscription's script, including the general 'vertical' stance of *mem*, the 'truncated' vertical shaft of *samek*, and the high junctions of the internal strokes of *šin*. The inscription chiseled into the stone sarcophagus of the Byblian king named Ahiram continues to be one of the most important for analyses of the early Phoenician script. This inscription derives from the same basic period as that of the bronze spatula but is substantially longer, with more consonants of the alphabet represented. The successive royal inscriptions of Yehimilk, Abiba'al, Eliba'al, and Shipitbaal also come from Byblos and provide data for a reliable script typology of the 10th-century Phoenician script (McCarter, 1975).

Figure 1 Bronze spatula (Phoenician).

The Phoenician script soon became an international script. For this reason, Kilamu (king of Sam'al in northern Syria) commissioned the production of a monumental inscription (9th century) in Phoenician (language and script), even though Phoenician was not the dominant local language. Moreover, the Anatolian (Neo-Hittite) regent Azitawadda also commissioned a Phoenician inscription (8th century) to parallel his (native) Hittite Hieroglyphic rendition. This inscription (from the site of Karatepe) is the longest of the Phoenician inscriptions. Significantly, early cursive Phoenician inscriptions are also attested, such as the (8th century) Kition bowl (Cyprus) and the ivory plaque from Sarepta (Lebanon), demonstrating that the Phoenician script possessed both cursive and lapidary traditions, both in the colonies and in the homeland.

During the succeeding centuries, the Phoenician script continued to be used quite widely. For example, the sarcophagus of the Sidonian king Eshmunazor II and the Byblian Stele of Yehawmilk (both 5th century) were inscribed with long Phoenician inscriptions, in a script that reflects substantial development from the early Phoenician scripts. Late Phoenician inscriptions (from the 3rd and 2nd centuries B.C.E.) have been found at various sites (Peckham, 1968). Moreover, Punic inscriptions are attested from various sites, such as Carthage and Hadrumetum, for a period of several centuries as well. A distinguishing feature of Punic inscriptions is the highly cursive nature of the script (neo-Punic is the term reserved for Punic inscriptions produced after the fall of Carthage to the Romans).

The Berber script (also called Numidian, Libyan, or Libyco–Berber) is often believed to have derived from Punic (or perhaps some South Arabian script). This script series consists of 22 letters. Most of the extant inscriptions are brief, nonmonumental texts. Many of the most informative Berber inscriptions come from Numidia, including some invaluable Berber–Punic bilinguals (2nd century B.C.E.). Furthermore, there are also some Berber–Latin bilinguals (ca. 2nd and 3rd century C.E.) (Chaker, 1984; Friedrich, 1957).

The Iberian script is most problematic. There are some bilinguals (Greek–Iberian and Latin–Iberian)

Figure 2 Stone El-Kerak inscription (Moabite).

with proper nouns; hence, the values of the letters are known. Moreover, two major divisions of the script are recognized: Northeast Iberian (written from left to right) and South Iberian (right to left). Nevertheless, a major problem is the origin of this 'script mélange.' Some have argued that the script is based on a Semitic script, some have argued that it is based on a Greek script, and some have suggested some sort of combination of these two positions (Anderson, 1988).

The Hebrew Script

The Phoenician script was the *Mutterschrift* (i.e., the foundational script from which another script developed) of the Old Hebrew script (a term used to refer to the Hebrew script of the Iron Age), as well as of Early Moabite (e.g., the Mesha inscription and the el-Kerak inscription) (Figure 2). Old Hebrew inscriptions, with a script that reflects distinct morphological features (i.e., from Phoenician) are attested for the late 9th and early 8th centuries. For example, excavations at Arad, Kuntillet Ajrud, Samaria, and Beth Shean have yielded early Old Hebrew inscriptions of the (late) 9th and early 8th centuries in numbers that are sufficient for detailed and reliable paleographic analyses of the early Old Hebrew script (Figure 3).

Among the features that distinguish the Old Hebrew script of this period from the Phoenician *Mutterschrift* of the same period are (1) a distinct curvature of the terminal component of the downstrokes of several Old Hebrew letters (e.g., *kap*, *mem*, *nun*, and *pe*), (2) *bet* consistently has a top-right (i.e., /) orientation, and (3) *taw* is consistently written with two strokes forming an x rather than something often approximating a + (Naveh, 1987; Rollston, 2005a). Significantly, Old Hebrew

Figure 3 Samaria ostracon 17 (Hebrew).

inscriptions from the late 8th, 7th, and early 6th centuries (from sites such as Gibeon, Mesad Hashavyahu, Horvat Uza, Lachish, and Arad) reflect continuing development of the script (that can be described in an empirical fashion; Rollston, 2003, 2005b). Note that the Arad ostracon drawn in Figure 4 derives from stratum VI–VII of the Tel and dates to the late 7th or early 6th century, and so reflects later developments within the Old Hebrew script of late Iron II (compare, for example, *he*, *yod*, *mem*, and *nun* of this Arad ostracon and the 8th-century Samaria ostracon).

It should also be affirmed that the Old Hebrew script, regardless of its internal diachronic developments, continues to retain various features that distinguish it from the Phoenician and Aramaic scripts of contemporary periods (Naveh, 1987; Rollston, 2005a). Finally, it should be noted that although the Aramaic script supplanted the Old Hebrew script, a form of the Old Hebrew script (often called 'Palaeo-Hebrew' script) persisted (e.g., Qumran and some Hebrew coinage) during the late Second Temple period (McLean, 1982; Tov, 2004). Nevertheless, the majority of the Dead Sea Scrolls (a major repository of texts of the late Second Temple period) are written in the 'Jewish script,' a script derived especially from Aramaic (Cross, 1961).

The Aramaic Script

The Arameans continued to use the 'prestige' Phoenician script for several centuries (cf. the Hadad inscription, the Panamu inscription, Bar Rakib, and Zakir of Hamat – all of the 9th century) (Figure 5). However, Aramaic inscriptions from the mid–8th century demonstrate that the (cursive) Aramaic script has separated from the prestige Phoenician script, reflecting developments that are not paralleled in the Phoenician *Mutterschrift*. Significantly, it is readily apparent that the Aramaic script rapidly became an international script (largely displacing Phoenician). Some of the most important evidence for the Aramaic

Figure 4 Arad ostracon 1 (Hebrew).

Figure 5 Deir ʻAlla inscribed stone (Early Aramaic).

cursive script series are the Hamat bricks, the Lion-Weights from Nineveh, and the Nimrud ostracon (all dating to the 8th century). The Sefire inscriptions (mid-8th century) are superb exemplars of a standard lapidary text (a treaty carved in stone) and exhibit the more conservative morphology of a lapidary script. The Assur clay tablets and the (lengthy, but elegant) Assur ostracon epitomize the developments of the 7th-century cursive. For the 6th century, the Saqqarah papyrus and the Hermopolis papyri reflect the standard Aramaic cursive script. Of course, the Aramaic from Elephantine provides substantial data for the script of the 5th century (Naveh, 1970; Porten and Yardeni, 1986–1999). Among the most prominent distinguishing features of the Aramaic script during these centuries (beginning in the late 8th century) are the following: (1) open-headed *bet*, *dalet*, and *reš*; (2) an open *ʻayin*; and (3) single barred *ḥet*.

Note that the Ammonite script became an independent national script for a time (separating from Aramaic), but this development was an ephemeral feature (Hackett, 1980; Rollston, 2005a). Aramaic and Ammonite inscriptions are attested at certain (Jordanian) sites, including Hisban and Deir Alla (Aufrecht, 1989).

It is also important to mention that the Aramaic script (and language) became quite prominent in Palestine during the Second Temple period (ca. 538 B.C.E.–70 C.E.). The term 'Jewish script' is used to describe the script that derived from the Aramaic script and became quite dominant during the Second Temple period, including for the writing of the majority of the Dead Sea Scrolls (Cross, 1961) and a number of inscribed ossuaries (Rahmani, 1994).

Concluding Notes on Phonology and Orthography

It should be stated that the *Mutterschrift* (i.e., Phoenician) was not entirely capable of reflecting some of the basic consonantal phonemes in Old Hebrew and Aramaic (i.e., consonants in Old Hebrew and Aramaic did not all merge at the same time and in the same manner as was the case in Phoenician). For example, the voiced interdental fricative /ð/continued to be preserved as a separate phoneme in Aramaic, but there was no Phoenician letter for it; hence, *zayin* was used at times for this phoneme, as was also *dalet*. Moreover, Old Hebrew preserved the voiceless lateral fricative /ś/, but there was no Phoenician letter for it; hence, the grapheme *šin* did 'double-duty' and was used for this phoneme as well (Garr, 1985). Scripts are, after all, frail conventions for symbolizing language and the act of borrowing a script necessitates the acceptance of various accommodations.

Finally, it should be noted that the early alphabetic scripts were employed to represent consonants, not vowels (hence, reconstructing the actual vocalization of Northwest Semitic is quite theoretical). The Phoenician script continued to be used to represent only consonants until very late times. The Aramaic script, however, reflects a major innovation: The consonant letters began to be used (ca. the 10th century) also to represent final (long) vowel sounds. For example, *yod* was used to represent final /ī/, *waw* was used to represent final ū, and *he* was used for the remaining final vowels. Soon this system was employed to represent medial (long) vowels in Aramaic as well. Hebrew began (ca. 9th century) to employ a similar system for the representation of (long) vowels, a system probably dependent on the

As early as the 8th century B.C.E., Assyrian palace reliefs depict scribes tallying war spoils in pairs. One scribe typically incises a tablet with cuneiform to reflect the tally in Akkadian while a second scribe records the same data in Aramaic with a pen and scroll. Aramaic had begun its rise to *lingua franca* status in the Near East. When the Assyrian empire dismantled the Levant's numerous Aramaean kingdoms and forcibly deported their citizens (9th to 8th centuries B.C.E.), it assured that Aramaic would become an international language on the ground as well as in prestige circles. The subsequent Neo-Babylonian (6th century B.C.E.), Achaemenid (6th to 4th centuries B.C.E.), and Parthian (3rd century B.C.E. to 3rd century C.E.) empires continued to employ the Aramaic script and (to varying degrees) language for administrative purposes (Naveh, 1970a). It was partly through these institutional frameworks that Aramaic was disseminated abroad and adapted to represent peripheral and still remoter languages.

Palaeographers traditionally divide the Middle Aramaic scripts (200 B.C.E. to 200 C.E.) into western and eastern branches. The western branch includes the scripts of Palestinian Aramaic and Nabataean. The Palmyrene and Hatran scripts represent the eastern branch of Middle Aramaic with Syriac, Elymaic, Mandaic, and (in a broader sense) Iranian Pahlavi the notable scripts of the Late Aramaic period (**Figure 1**, cols. 21–32).

Western Middle Aramaic Scripts

It is necessary to discuss the Persian cultivation of the Aramaic writing system in order to appreciate the means by which the scripts later diversified during the Middle Aramaic period. Official or Imperial Aramaic designates the historical dialect of the language that broadly characterizes documents from the Achaemenid period. The main corpora include about one hundred papyri from Egypt and numerous incised endorsements on cuneiform tablets written in Akkadian or Elamite from Mesopotamia, although a number of monolingual Aramaic tablets have also surfaced. Thus, for substantive linguistic purposes, we mainly look to the Egyptian papyri, the geographic restriction of which raises caveats about the representative character of their dialect(s) (Byrne, 2005). Most Aramaists consider the Official Aramaic of the papyri to represent an eastern dialect of the language. For palaeographic purposes, there are enough similarities of form and ductus between these papyri and the incised tablets from Mesopotamia to warrant the tentative designation of an institutional script. This implies a chancery education for scribes working in Achaemenid administrative circles. Cross (1974) has argued that this chancery hand, best represented by the formal script of the Arsames correspondence (government communiqués on leather scrolls), served as progenitor of what he termed the 'bookhands' of the Qumran documents from the Dead Sea caves. The discovery of the Samaria papyri has provided evidence that seems to validate this view (Gropp *et al.*, 2001; Byrne, 2005). These papyri represent a trove of 4th-century B.C.E. legal documents belonging to Samaritan elites presumably killed during Alexander's invasion of the Levant. They provide a good palaeographic link between the Egyptian chancery script and the formal hands of the Qumran script. This chain of development speaks to the enormous palaeographic influence of the administrative script, although we know little about the circumstances of the chancery education or opportunities for its emulation. The 5th-century papyri from Egypt include documents written by Jewish scribes from the military colony of Elephantine in a less formal cursive script (Naveh, 1970a), but one imagines that such scribes routinely witnessed correspondence in the formal hand of Persian administrators.

With a few exceptions, documents from Qumran written in Aramaic exhibit a script undifferentiated from most written in Hebrew, and so fall within the category of the so-called Jewish square script. The square script formed the basis for the later Rabbinic (Hebrew and Aramaic), Medieval (Hebrew and

They provide a good palaeographic link between the Egyptian chancery script and the formal hands of the Qumran script. This chain of development speaks to the enormous palaeographic influence of the administrative script, although we know little about the circumstances of the chancery education or opportunities for its emulation. The 5th-century papyri from Egypt include documents written by Jewish scribes from the military colony of Elephantine in a less formal cursive script (Naveh, 1970a), but one imagines that such scribes routinely witnessed correspondence in the formal hand of Persian administrators.

With a few exceptions, documents from Qumran written in Aramaic exhibit a script undifferentiated from most written in Hebrew, and so fall within the category of the so-called Jewish square script. The square script formed the basis for the later Rabbinic (Hebrew and Aramaic), Medieval (Hebrew and

Aramaic), and modern Israeli Hebrew scripts, but it does not in fact derive from Hebrew characters of the Iron Age (Cross, 1961). Perhaps as early as the late Persian period (though some argue Hellenistic), Jewish scribes appropriated the Aramaic script to write Hebrew, and the subsequent development of that adoption defined the familiar square script of Roman-period ossuary inscriptions (Rahmani, 1994), Talmudic and Medieval Jewish literature, Yiddish and the modern font text employed to represent Israeli Hebrew. There was a revival of the Iron Age Hebrew script in the Maccabaean period (2nd century B.C.E.) and in some Qumran texts, but this choice may have been more ideological than functional (and restricted in any case without any successive palaeographic developments). Scholarly literature inconsistently uses the term 'Paleo-Hebrew' to refer both to this archaizing revival and to the referent archaic Iron Age script. This ambiguity needlessly confuses palaeographic discussions, and perhaps the term should be abandoned. Given its prominence in extant Rabbinic manuscripts of the Gaonic and later periods (Goldberg, 1987), the Jewish square script must also have served Amoraic scribes and the late Tannaitic compilers of the Mishnah and Tosefta, whether those texts were composed in Aramaic or Hebrew.

By the 3rd century B.C.E., the earliest Nabataean inscription shows Aramaic beginning to supplant the Thamudic script among Arab scribes living in and around the southern Transjordanian rift valley. The Nabataean kingdom centered at Petra cultivated this script for official purposes, although the spoken language remained Arabic. Short votive, burial, legal, and numismatic inscriptions meet innumerable graffiti to constitute a Nabataean corpus exhibiting gradual development of formal and free cursive styles (Naveh, 1987). Trajan's annexation of Arabia Felix into the Roman empire in 106 C.E. probably diluted much of the institutional imprimatur the script enjoyed, but Nabataean shortly proceeded to evolve ligatures typical of durable cursives (and more formal incised examples continue as well). Over the next couple of centuries, one observes the gradual infiltration of Arabic terms into the texts alongside the Aramaic. Extant Nabataean specimens do not appear later than the 4th century C.E., but the palaeographic affinities with 6th-century pre-Islamic Arabic affirm that the Nabataean cursive was the parent of the Classical Arabic script (Gruendler, 1993). This cursive parentage accounts both for the ligatured nature of Arabic and for the introduction of diacritics for facilitated reading (Naveh, 1987). Despite the arguments of some scholars (e.g., Klugkist, 1986) that Nabataean may underlie the origins of the later Mandaic script (which pervades the incantation bowls from Mesopotamia) and so have witnessed a migration of intellectual property, Naveh (1970b) argues convincingly that the casual resemblance of the few similar graphs is attributable to discretely intuitive ductus rather than ancestry. One properly credits the eastern branch of Middle Aramaic for primeval Mandaic.

Eastern Middle Aramaic Scripts

Arabs living in the Roman city of Palmyra adopted the Aramaic writing system initially to bureaucratize the ballooning commercial activity of caravans visiting this central Syrian oasis (see bibliography in Hillers and Cussini, 1996). The Arabic language was virtually never represented by the script, however, which faithfully records an Aramaic dialect in all epigraphic genres. The vast majority of the surviving inscriptions are votive or epitaphs, rather than contractual, which is attributable to the perishable nature of media (papyri or leather) employed for commercial purposes. The result is a preponderance of incised stone epitaphs, occasionally accompanying glorious artistic scenes or busts, that predictably privilege a lapidary form of the script over the less represented cursive. The cursive occasionally creeps into the funereal epigraphs, but cursive is generally rare even when far-flung examples from Rome and Dura Europos are considered. Some epigraphers have not genuinely appreciated the import of these different scribal styles. Klugkist (1983) has misunderstood the relationship between media and ductus, for example, and eschewed the palaeographic value of the lapidary specimens. Lapidary scripts tend toward the conservative developmentally, but accompanying dates on several Palmyrene inscriptions have confirmed the reliability of the script's contribution to typological knowledge and chronology. The palaeographic correspondences between Palmyrene and the Syriac script of the Late Aramaic period suggest the existence of an ancestor script in common, rather than a linear, filial relationship between the two writing systems. Naveh (1975, 1987) has posited a Seleucid incarnation of this Aramaic script for the 3rd century B.C.E., and some epigraphs from the 2nd century B.C.E. indeed seem to support the reconstructed existence of such an administrative script for the Hellenistic state.

The Mesopotamian oasis of Hatra has produced a wealth of Aramaic inscriptions dating from the Seleucid period to the 3rd century C.E. (Degen, 1978; Aggoula, 1991). The Hatran script represents a local customized form of Aramaic writing unrelated to the Palmyrene/Syriac subset of the eastern branch of Middle Aramaic (Naveh, 1972). Many of these

Figure 1 A chart of the West Semitic scripts drawn by Julius Euting in 1877 (most recently reprinted in *Israel Oriental Studies 20* [2002]: 112–115; reproduced courtesy of the publisher, James E. Eisenbraun).

epigraphs are dated internally, which affords a more precise palaeographic treatment of the script's history. The script was extremely conservative developmentally with negligible alterations during the 140-year period of the internal dates (Naveh, 1987). Armenian and Georgian appropriations of the script introduced respective modifications, but the Hatran scribes themselves championed a consistency of reproduction that speaks to a tightly controlled curriculum.

Aramaic and the Indian Scripts

Brāhmī and Kharoṣṭhī are the earliest scripts of the Indian subcontinent to appear following the demise of the Indus Valley script. They record Prakrit or Middle Indo-Aryan languages. Scholars have long recognized the indebtedness of these scripts to the West Semitic writing system (Salomon, 1998), although some Indologists (Dani, 1986) have stressed Indian innovation in the form of modifications to represent syllabic vocalization. The recovery of six Aśokan inscriptions in Aramaic confirms the long-held suspicion that Aramaic was the parent script of Brāhmī, while the new Gandhara epigraphs speak strongly for a palaeographic relationship between Aramaic and Kharoṣṭhī (Salomon, 1999). We have no extant specimens of these scripts earlier than the 3rd century B.C.E., but the palaeographic points of contact with Aramaic argue for a considerably earlier date for the adoption of Brāhmī (McCarter, 1992) and Kharoṣṭhī under Achaemenid chancery auspices. The recent discovery of an 8th-century B.C.E. Aramaic royal inscription from Bukān (Lemaire, 1998), well beyond the borders of the Assyrian empire, may provide a precedent for such scribal transmission to parts far afield.

By 1100 B.C.E. the seafaring Semitic-speaking Canaanites of the eastern Mediterranean had a writing system consisting of 22 letters representing consonants. The Greeks came into contact with this people between the 11th and 8th centuries B.C.E. and named them 'Phoenicians' for the purple dye for which they were famous. Neighboring Semitic-speaking peoples, the Hebrews, Moabites, and Arameans, also used this consonantal alphabet for their closely related languages. The Phoenicians seem most directly responsible for transmitting the consonantal writing system to the Greeks, and from them the Etruscans and Romans would adapt it a few centuries later. In the Middle Ages, the Europeans would make variations on the Latin version, and the Slavs would fashion a version of the Greek alphabet. Written Moabite had a fairly short literary life in the first half of the first millennium B.C.E., and in the second half of that millennium, the Hebrews adopted the Imperial Aramaic style of writing these letters. In the first centuries C.E. the Arabic-speaking Nabateans also adopted a version of the Aramaic script, and the modern cursive Arabic script would arise with the rise of Islam in the second half of the first millennium C.E.

This Semitic system represented consonant segments only and not vowels. Peter Daniels has termed such a selectively segmental writing system an 'abjad,' based on the first four letters ⟨', b, j, d⟩ of the Arabic name for this system (in Arabic the sound /g/ shifted to /dʒ/.). Hebrew and Aramaic also used this writing system, but even though they had slightly larger consonant inventories than Phoenician, they created no new letters to meet the need. In succeeding centuries, ironically, consonant mergers in these languages would make a more adequate grapheme–phoneme fit. That ancient abjad has four modem descendants in the Middle East used for writing four Semitic literary languages: Hebrew, Arabic, and two varieties of Aramaic called Syriac and Mandaic (Figure 1 of **Asia, Ancient Southwest: Scripts, Middle Aramaic** cols. 27, 28, 31, 32, 57). (Later adaptations of these scripts for non-Semitic languages – the Hebrew abjad for Yiddish, Ladino, and Judeo-Arabic, among others; the Arabic abjad for Pashto, Urdu, Ottoman Turkish, Kurdish, and Uyghur – became increasingly alphabetic, that is, they revalued some consonant letters to represent vowel segments more consistently on an equal plane with consonants. The details lie outside the scope of the present article.)

Text proceeded then, as now, from right to left across the writing surface. (Compare modern Amharic in Ethiopia, descended in the Christian era from the Old South Arabian cousin to the Phoenician abjad, which has reversed direction to left-to-right.) The original letters had one form for all positions in a word. The modern descendants (except Mandaic) have developed allographs for word-final position irrespective of the type of word or its position in the sentence. The current 'square' shapes of Hebrew developed as varieties of Aramaic toward the end of the first millennium B.C.E. Along with this, four Hebrew letters, ⟨k, n, p, ṣ⟩, kept their downward stroke word-finally but bent it leftward when followed by another letter in the same word, that is, word-initially and word-medially. Thus the forms now designated 'final' forms are actually the original forms, and the nonfinal came later. The originally jagged line of ⟨m⟩ closed into a square word-finally and a more rounded figure with an open lower left corner nonfinally. As Arabic developed several hundred years later, its cursive style came to finish all but four of its letter shapes – ⟨', w, d, r⟩ (and the last two add a dot for ⟨ð, z⟩ respectively) – with a flourish or tail. Syriac, also written in a cursive style, has somewhat fewer distinct final forms. (Compare the later Greek-Roman-Cyrillic family of alphabets with complete parallel letter sets called upper and lower case. Upper case is usually reserved for sentence-initial position for all words and word-initial position for certain kinds of words and lower case for the rest of the word and the rest of the words in the sentence.)

These superficial changes in the letter shapes of each of the four systems have not altered their basic principles of operation: one symbol still represents one speech sound, specifically consonant phonemes. The dual function of the letters for glide consonants will be discussed below.

Consonant Inventories

The stock of 22 letters for the consonant phonemes of Hebrew and Aramaic remained stable till the end of the first millennium B.C.E. The six nonpharyngealized stops of these languages, /p, t, k, b, d, g/, had phonetically postvocalic fricative alternates, and the script did not represent them. (The chronology of the rise of that stop/fricative alternation is still controversial and arose in Hebrew and Aramaic at different times.) Arabic script, developing in the middle of the first

millennium C.E., increased the letter inventory to 28 by adding one, two, or three dots to existing consonant letters. Some of these dots also served to distinguish several letter shapes that had become too similar. The movement toward vowel dots in these scripts during the second half of the first millennium C.E., to be discussed below, also included for Hebrew and Aramaic/Syriac the practice of distinguishing the stop/fricative alternates by a dot: Hebrew opposed a dot in the letter for the stop to the letter without a dot for the fricative, while Syriac placed a dot above and below respectively.

In Hebrew the increasing phonemicization of these stops and fricatives has still not led to the creation of new letters. Modern Hebrew /f/, for example, is both an automatic variant of /p/ and also a phoneme in foreign borrowings. Although this does not change the letter, it certainly changes the distribution and the modern speaker's ability to read unfamiliar text. Formerly an older borrowing such as *pilosofiya* 'philosophy' had word-initial /p/ and postvocalic /f/, but in many modern people's speech it has been in a sense reborrowed as *filosofiya* with initial /f/. Hebrew spelling cannot show this without these additional dots, with which it in any case dispenses in normal modern writing.

Modern Hebrew and Syriac, similarly, have both experienced phonological reduction through consonant mergers – for example, loss of pharyngealized dentals in Hebrew (older pharyngealized /ṭ/ merging with plain /t/) or loss of pharyngeals in both languages – but retain all the historical letters, creating a largely historical, morphological spelling. The only new graphic element in modern Hebrew is the diacritic apostrophe for new palatal phoneme in foreign borrowings. Two existing dentals ⟨ṣ, z⟩ and the velar ⟨g⟩ add this mark to converge on the palate as /tʃ, ʒ, dʒ/, respectively.

The original ABGDH order of the letters as preserved in some Hebrew acrostic texts (e.g., Psalm 119) came to serve the dual purpose of numerical representation, possibly one of the factors that helped maintain the order. Arabic with its new dotted consonant letters reorganized the alphabet by letter shape. This results in an initial sequence glottal stop, b-t-θ, j-ḥ-x, d-ð, r-z, s-ʃ, ṣ-ḍ, ṭ-ẓ, '-ġ, f-q, k, l, m, n, h, w, y. Nonetheless, modern Arabic can still resort to the old 'Semitic' order for numbering and outlining.

Vowel Representation with Existing Resources

Toward the end of the second and beginning of the first millennium B.C.E., each letter represented a single consonant segment. Aramaic, early in the first millennium B.C.E., however, extended the letters for the glide consonants ⟨y, w, h, '⟩ to represent long vowels as well, a technique termed *matres lectionis* 'mothers of reading' or 'reading aids.' The palatal glide letter ⟨y⟩ represented the front vowels /iː/ and /eː/; the labial glide letter ⟨w⟩ covered the back vowels /uː/ and /oː/. Both ⟨h⟩ and ⟨'⟩ signaled the nonhigh vowels /aː/ and /eː/ but only word-finally. Hebrew eventually followed in this practice as well and continues till today. Short vowels found no representation in this early period. Interestingly, Phoenician itself did not participate in this development and remained solely consonantal for the duration of its existence (its later colonial development, called Punic, did begin to represent vowels toward the end of its existence). It is still a matter of discussion whether the Semites innovated this extension independently or were influenced by the Greeks, who, in borrowing the Phoenician abjad, revalued the glide letters as the familiar vowel letters A-E-I-O-Y/U on an equal graphic plane with the consonants. (Since the Greeks did this consistently for all vowel segments, their system is regarded as the first 'true alphabet' in the sense of representing all segments by equal characters.)

Over a millennium later the Arabic script emerging in the age of Islam retraced these same steps for its three-vowel system: ⟨y⟩ for /iː/, ⟨w⟩ for /uː/, and, in a new development, ⟨'⟩ for /aː/ anywhere in the word. The only short vowel represented is /a/, by ⟨h⟩ but only word-finally and specifically the feminine singular noun ending, e.g., *madiːna* 'city' written ⟨mdynh⟩; *kataba* 'he wrote' written ⟨ktb⟩; *rusuːl* 'messenger' written ⟨rswl⟩; *kitaːb* 'book' appears as ⟨kt'b⟩. Under some circumstances, especially in morphological alternation with the diphthong /ai/, ⟨y⟩ serves for final /aː/ as in *bana* 'he built,' written ⟨bny⟩, compared with the *banaytu* 'I built,' written ⟨bnyt⟩. Post-Biblical Hebrew and Aramaic incorporated *matres lectiones* as a matter of course but did not insert them into the existing Biblical text.

Innovations in Vowel Representation

Preserving the correct pronunciation of sacred texts in these languages became a major occupation during the second half of the first millennium C.E., and each society introduced systems of adlinear dots and dashes superimposed over the canonical consonantal text as consistent and nearly unambiguous representations of vowel segments, a technique called 'vocalization' or 'pointing.' Texts in these languages, then, are designated un/vocalized or un/pointed, that is, with or without maximal vowel representation beyond the *matres lectionis*. The Syriac grammarians

pioneered this technique. Several generations of Hebrew scholar-copyists with schools in Tiberias and Babylon were known as the Massoretes ('preservers and transmitters', from Hebrew *masora* 'tradition'), and their texts preserve the Massoretic text of the Hebrew Bible. Three quite different vocalization systems – Palestinian, Babylonian, Tiberian – were in use, but Tiberian emerged as the one standard system. Arabic tradition also had ways of verifying and preserving the revealed text of the Qur'an. Vowels are thus represented by signs of a qualitatively different nature from consonant signs (and *matres lectionis*). The 'letters' provided a consonantal skeleton and the superimposed dots represented the vowel segments.

Hebrew and Syriac devised dots for all their vowel qualities and quantities and, unusually, recognized both phonemes and allophones, particularly for the mid vowels. The *matres lectionis* represented long vowels, but the Syriac and Hebrew systems amplified their representation to include nonfinal /aː, eː/ and for the first time included all the short vowels as well. The Hebrew [h] glide represented a vowel only word-finally and specifically the nonhigh vowels /a, e/ as well as a very few instances of /o/. The other crucial feature of this 'vocalized abjad' is that the dots are optional. Modern Hebrew, for example, uses them only in Bible texts, dictionaries, poetry, children's books, and some textbooks, and indeed they represent a much richer vowel system than that of modern Israeli Hebrew.

Eastern and Western Syriac vocalized on similar principles, recognizing long and short vowels somewhat differently, but the visual difference was quite apparent. Eastern Syriac used dots like Hebrew, but Western Syriac, being closer to the Greek sphere of influence, actually used small Greek vowel letters above its consonant letters.

Mandaic has moved farthest away from the 'abjad' principle. It spells virtually all its vowels with *matres lectionis*, retracing the steps of the Greeks in creating a 'true alphabet' with equal symbols for consonants and vowels. One can observe the same kind of development in the Arabic script adaptations for, e.g., Kurdish and Uyghur.

Earliest Evidence

Among the late second millennium tablets excavated at Ras Shamra, the ancient site of Ugarit, a dozen or so, referred to as abecedaries, simply contain the thirty-odd letters of the Ugaritic cuneiform alphabet in a certain order. Almost all of these are in an order beginning 'ʔ b g (ḫ) d . . .' homologous to the 'ʔ b g d . . .' order familiar from the Hebrew alphabet, and distantly reflected in the 'a b c d . . . '/'α β γ δ . . .' of the Roman/Greek alphabets. One of these texts, however, excavated in 1988, which is duplicated by a tablet found far to the south, at Beth Shemesh in contemporary Palestine, shows an order beginning 'h l ḥ m . . .' (Bordreuil and Pardee, 1995). This is exactly the beginning of the traditional order of characters in Ethiopic script (see the traditional order in **Figure 4**), and in both the Ancient South Arabian and Ancient North Arabian scripts, as known from both native abecedaries and other evidence (see Ryckmans, 1985; Irvine and Beeston, 1988; cf. Macdonald, 2004a, 494). **Figure 1** shows the intuitively clear formal relationship of the Ancient Arabian scripts and Ethiopic to each other. Although the three 'alphabetic' orders show some important differences in the further ordering of some of the subsequent signs (see

pioneered this technique. Almost all of these are in an order beginning 'ʔ b g (ḫ) d . . .' homologous to the 'ʔ b g d . . .' order familiar from the Hebrew alphabet, and distantly reflected in the 'a b c d . . . '/'α β γ δ . . .' of the Roman/Greek alphabets. One of these texts, however, excavated in 1988, which is duplicated by a tablet found far to the south, at Beth Shemesh in contemporary Palestine, shows an order beginning 'h l ḥ m . . .' (Bordreuil and Pardee, 1995). This is exactly the beginning of the traditional order of characters in Ethiopic script (see the traditional order in Figure 4), and in both the Ancient South Arabian and Ancient North Arabian scripts, as known from both native abecedaries and other evidence (see Ryckmans, 1985; Irvine and Beeston, 1988; cf. Macdonald, 2004a, 494). Figure 1 shows the intuitively clear formal relationship of the Ancient Arabian scripts and Ethiopic to each other. Although the three 'alphabetic' orders show some important differences in the further ordering of some of the subsequent signs (see

discussion in Daniels, 1997), the existence of these 'South Semitic'-type abecedaries at that period in Ugaritic, together with the clear formal relationship of at least some of the South Semitic characters to their North Semitic counterparts (compare Figures 1 and 3), show that the South Semitic writing tradition is not only quite ancient, but also shared, at least at one point in time, a cultural context with the North Semitic tradition.

Epigraphic South Arabian

The earliest contextualizable attestations of the South Semitic script are in monumental inscriptions which begin to appear in the 8th century B.C.E. in a series of city-states – Maʿin, Saba ('Sheba'), Qataban, Hadramawt – along wadis draining the Yemeni and eastern Omani highlands into the southwestern and southern edge of the great Arabian desert, the Empty

Figure 2 Example of ''classic'' South Arabian inscription (Nebes N & Stein P [2004]. 'Ancient South Arabian.' In Woodard R (ed.) *The Cambridge encyclopedia of the world's ancient languages.* [Cambridge. Cambridge University Press], 457, Figure 15.1).

Quarter. Stemming from a long second millennium tradition of urbanization and agriculture on the terraced and irrigated highlands, these desert-edge polities derived much of their influence and prosperity from being well situated to control the various stages of the incense route between the indigenous regions for frankincense and myrrh to their point of transshipment up the Hijaz to the Mediterranean world.

The earliest Ancient South Arabian texts are already cleanly incised on prepared stone surfaces with uniform geometric characters, whose consistent transformations can be tracked across generations of scribal ductus (Figure 2). Words are neatly separated by a vertical line serving as word-divider, but there is no other consistent punctuation. Compared with some North Semitic writing systems, only a restricted use is made of consonants such as *w, y, ʔ, h* to indicate vowel quality or length. The writing of many of the earliest Sabaic texts, from the 8th to the 4th centuries B.C.E., is *boustrophedon*, that is, starting out on the top line in one direction, the next line will be written in the other direction, and so on (as the ox plowing a field turns up one row and down the next). Although it is used in shorter texts, the formative context of this writing style may have been very long inscriptions running the length of a building, where the reader would not be obliged to go all the way back to the other end of the structure to continue to follow the text. After the 4th century, however, Epigraphic South Arabian is written consistently from left to right (again, as opposed to North Semitic systems). According to the dating system that eventually evolved, the last of the South Arabian monumental texts comes from the mid 6th century (554–559) C.E.

It has always been supposed that once a writing system was developed for the various South Arabian dialects it would have been used for utilitarian administrative and economic purposes. Indeed, many Ancient Near Eastern parallels suggest that it would have been put to use for utilitarian purposes first, and only then adapted for monumental, religious, and cultural ends. However, apart from ubiquitous graffiti, which attracted little interest next to the many thousands of beautifully written monumental texts, almost nothing was known about eventual practical applications of Ancient South Arabian writing until it was realized in the 1970s that markings on thin wood sticks or strips – often the central spine of palm fronds – actually represented a cursive form of Ancient South Arabian. Since then several thousand of these have been identified, most apparently dating from the 2nd and 3rd centuries C.E. Written in a highly transformed, cursive writing system and dealing with an entirely different range of subject matter – inventories, loans, letters, etc. – their interpretation has been slow and difficult. But the several dozen that have been published have already thrown new light on the language – for example, in giving abundant attestations of second person forms, hitherto virtually absent from the highly stereotyped

f0015 **Figure 3** North Arabian scripts (Macdonald, 2004a, 496, Figure 16.3).

formulae of the monumental texts, which refer to participants in recorded activities exclusively in the third person.

Early Epigraphic North Arabian

Ancient North Arabian is a group of interrelated dialects attested in well over 40 000 inscriptions, for the most part graffiti, from settled ('oasis') and nomadic populations in central and north Arabia, southern Syria, and eastern and southern Jordan, between the 8th century B.C.E. and the 4th century C.E. Ancient North Arabian dialects are themselves closely related to, but distinct from, Arabic 'proper' – Classical, Qur'anic, and Modern – and Arabic and Ancient North Arabian both belong to a branch of Semitic distinct from that of Ancient South Arabian (on the complex classification questions involved here see Macdonald, 2004a).

However distinct linguistically Ancient Northern and Southern Arabian may have been, they are clearly both using the same South Semitic writing systems (compare **Figures 1 and 3**). It is not certain to what extent the system used by the various Ancient North Arabian dialects was simply borrowed as such from their Ancient South Arabian contacts in the incense trade (as they shuttled the precious merchandise between Yemen and the Mediterranean world), and to what extent it may represent an independent continuation of a South Semitic writing tradition in the northern part of its range. Some features of writing style are distinctly nonsouthern, for example, a predominantly right-to-left direction of writing in the great oases, while many of the nomadic graffiti are written in any direction, according to the whims of the writer and/or the disposition of the ad hoc writing surface. On the other hand, certain oasis monumental inscriptions are boustrophedon, and use word-dividers. An absence of the use of consonants as auxiliary vowel indicators is common to both Southern writing traditions.

Ethiopic

The genetic relationship between Ancient South Arabian and Ethiopic Semitic language groups (and Modern South Arabian, which in any case has no writing tradition) is at least as complicated as that between Ancient South Arabian and Ancient North Arabian. However, in this case, the writing system as well is clearly South Semitic (see **Figure 1**). Moreover, here it seems fairly certain that it was Ancient South Arabians who were the bearers into Ethiopia of this writing system. It is clear that Ancient South Arabian trader-colonists had established by the 5th century B.C.E. urban centers on the Ethiopian highland with typical South Arabian religious and cultural institutions, including religious buildings with typical Ancient South Arabian monumental inscriptions.

The cultural relationship and balance of power between Ethiopia and South Arabia shifted back and forth in the centuries succeeding first colonization, and by the 1st century C.E. Aksum, a powerful city-state on the Ethiopian highland not far from an earlier Ancient South Arabian settlement, exercised tight control over commercial traffic in the southern part of the Red Sea. Monumental inscriptions appear written in Ge'ez, the Ethiopic Semitic language of Aksum, with distinctly Ethiopian character shapes. The earliest inscriptions are in a nonvocalized script, completely isomorphic to the script of Ancient South Arabian – in fact a few inscriptions, mistakenly called bilingual (or trilingual if they also involved a parallel version translated into Greek), have the same Ge'ez text written in Ethiopic and in South Arabian characters. At one point, toward the middle of the 4th century C.E., a king named Ezana, whose earlier inscriptions had been polytheistic (involving in part deities from the South Arabian pantheon) and unvocalized, begins to write inscriptions that invoke a monotheistic god *ʔəgziʔabḥer* 'Lord of the Earth' (who is or becomes identified with the Christian god; a similar process took place over a longer period of time in Southern Arabia).

At this point a capital development takes place in the writing system, the creation of a vocalization system, and in a way that is completely at variance with the evolution of vowel notation systems in other Semitic alphabets. Instead of indicating vowels by line or point diacritics, as in Hebrew or Arabic, or by above-line or under-line vowel symbols, as in Syriac, a vowel following the consonant is indicated by modifying, more or less consistently across the system, the basic shape of the consonant symbol itself. Each of the twenty-five consonant symbols is provided with six variants, making a total of seven shapes for the consonant followed by one of the seven vowels of Ge'ez: *ä u i a e ə o* (in the traditional syllabary order). The base shape was reinterpreted as C + ä, and the others were assigned in the traditional order, giving *Cä Cu Ci Ca Ce Cə Co*. The four labiovelars q^w $ḫ^w$ k^w g^w represent a special case, since (1) they could not be followed by a rounded vowel *u o* and (2) they apparently had no base shape in the unvocalized alphabet. For these phonemes a graphic representation was created by making five additional variants on the base *q ḫ k g* shape. Altogether this modification process yielded out of the twenty-five character alphabet a 257×7 (= 175 member) main syllabary grid, plus a 47×5 (= 20 member) secondary

sub-syllabary; a j̄ was added as well (Figure 4). In addition the writing system had, continuing a South Arabian tradition, a word-divider, which became two vertically aligned dots in the Ethiopic system.

It is sometimes suggested that the rise of the vowel system was caused by the necessity of a fully vocalized writing system for the translation of the Bible that followed on the conversion of Ethiopia to Christianity. It should be pointed out, however, that if the vocalized monotheistic monumental texts are indeed correctly dated to the 4th century, these texts antedate by at least two centuries the arrival of the refugee Syrian monophysite monks who are credited in the Ethiopian tradition with translating the Bible into Ge'ez. In any case the monumental tradition weakened considerably after Ezana, and a long Dark Age ensued, corresponding roughly to the Islamic conquest. This was a period, lasting up until the 11th century, of nearly absolute isolation of Ethiopia from the Mediterranean, and during this time virtually no manuscripts are known. When the manuscript tradition resumes, we see again that the vocalized writing

system known from the 4th century is the sole norm for writing Ge'ez. It is a writing tradition that continues uninterrupted into the present, the sole surviving representative of the South Semitic writing tradition.

Although Ge'ez is still used up to the present time as a written ecclesiastical language, from the 17th century on, and increasingly since the end of the 19th century, modern Ethiopic Semitic languages, and especially Amharic and Tigrinya (Tigrigna), the most important Ethiopic Semitic national languages of Ethiopia and Eritrea, respectively, have become standardized written languages and the principal normal vehicles of administration, mass media, and education. The traditional syllabary is viable for both of these languages because both maintain the 7-vowel system of Ge'ez. Whereas some distinctions present in Ge'ez were lost in the consonantal systems (and indeed had begun to be lost in late inscriptional Ge'ez), the written consonant inventory of Ge'ez is maintained intact, with characters representing merged phonemes, such as s and š functioning as allographs. In fact, in Amharic and Tigrinya (as well as most other modern Ethiopic Semitic languages) a new phoneme š emerged, as did a whole series of new palatal consonants. For these, new graphemes were systematically created where possible by placing a 'hat' on top of the corresponding nonpalatalized consonant. (Similar means were used to create a 'v' out of a spirant 'b,' and an 'x' out of a spirant 'k,' where required.)

Thanks to a minimal adaptation, the continued survival of the South Semitic writing system seems assured in the case of Amharic and Tigrinya, and perhaps for a few other Ethiopic Semitic languages whose use is being encouraged in local administration and education. However, many of the new written languages of Ethiopia, in particular the widely spoken Cushitic language, Oromo, having successfully resisted earlier political and cultural pressures to use the traditional syllabary, are resolutely proceeding with Latin-character-based writing systems.

Introduction

A number of disparate writing systems were devised between the 6th and 17th centuries for several non-Chinese languages in states founded on or near traditionally Chinese territory: the Khitan, Jurchen, and Tangut scripts, inspired by Chinese script; Turkic runiform, Old Uighur, Mongolian, and Manchu scripts, descended from Soghdian scripts; and the 'Phags-pa script, adapted from Tibetan script (*see* **Tibet: Scripts**). Earlier Inner Asian scripts are mentioned in Chinese sources, especially that of the Toba (Tabghach) Wei state of northern China (386–534), but they seem to have left no remains. While many of these scripts have been superseded or have died out, the Mongolian and Manchu scripts survive to this day. The term 'Inner Asia' is here to be taken in a loose cultural sense to refer to steppe-based nomadic societies in the Chinese cultural sphere and Buddhist or animist in religion, in the steppe regions east of Islamic Central Asia. The languages of Islamic Central Asia are predominantly Turkic and Indo-Iranian (Yakut is the only significant non-Islamic Turkic language) and as part of the Islamic world have been heavily influenced by Persian and Arabic and have been written in Arabic script since Islamization. Inner Asian languages, on the other hand, are Mongolic, Tungusic, and Sino-Tibetan, and the development of their scripts was shaped by Chinese ideals of statecraft and by religion (chiefly Buddhism).

The writing systems predating the Mongol empire – Khitan, Jurchen, Tangut, Turkic, and Uighur – were created at the behest of non-Chinese rulers of states containing substantial sedentary populations, primarily Chinese, who continued to be governed in their native languages by traditional sedentary administrations. (Mote, 1999: 39). These states were rivals of several Chinese dynasties that demanded from them the traditional signs of submission (e.g., the use of the current dynastic calendar and reign-year titles); promulgating a non-Chinese writing system for the elite language signified the rulers' legitimacy and equality in Chinese terms. Similarly, the patronage of Buddhism, which the Chinese elite viewed as a foreign doctrine despite its popularity among the Chinese people, secured non-Chinese rulers the support of a universalist religion with a highly educated clergy claiming great magical power. (Mote, 1999: 43–44, 398–399).

However, it was only when the ruling peoples became sedentary that much imaginative literature came to be written – aside from translations of the Buddhist scriptures – among the Uighurs after the 9th century, and probably among the Tanguts. Thus, the great part of what survives in the other pre-Mongol scripts consists of inscriptions and translations of Chinese and Uighur Buddhist texts. The situation in the early Mongol empire was somewhat different, for the Mongol emperors saw themselves as ruling by sheer right of conquest and seem to have adopted writing purely for pragmatic reasons. After the end of Mongol rule in China (1368), however, Mongol rulers increasingly patronized Buddhism, which ensured the survival of Mongolian script after the 'Buddhist Renaissance' of the 16th century spread *Ge-lug-pa* ('Order of Virtue', known colloquially as 'Yellow Hats') Tibetan Buddhism to the Inner Asian steppes. Despite the prestige of Tibetan, Mongolian Buddhist terminology to this day remains a mixture of native terminology and Sanskrit, Tocharian, Soghdian, Uighur, Chinese, and even Greek loanwords. Mongolian also served as the language of diplomacy north of the Great Wall from the 15th century on; because of its religious and political significance, the script was adopted and reformed by the Manchu rulers as part of their effort to portray themselves as the legitimate successors of the Mongolian Great Khans and Ming emperors and as patrons of Tibetan Buddhism (Mote, 1999: 786–787).

Sinitic Inner Asian Scripts

Khitan and Jurchen (Chinggeltei, 2002)

The Khitans, a nomadic people of Manchuria who appear to have spoken an early Mongolic language, were unified in 907 and expanded to rule the Inner Asian steppes and North China south to the Yellow River by the 950s (Mote, 1999: 56–69). Their state, the Liao, fell to their former subjects the Jurchens between 1113 and 1125, though a member of the Khitan imperial family escaped to found a state in Central Asia, Kara Khitai ('Black/Great Khitans') or Western Liao, that lasted from 1131 to 1211 (205–206). The Jin (Chinese for 'gold') state of the Jurchens, a sedentary people of northeastern Manchuria who spoke an early form of Manchu, ruled North China until their destruction by the Mongols between 1213 and 1234. Abaoji, the Liao founder, ordered the creation of a Khitan script in 920, the Khitan large script; this was succeeded in 925 by the Khitan small script. Following the example of the Khitans, the Jin founder Aguda ordered the creation of the Jurchen large script

in 1120, supplemented by the Jurchen small script in 1138. Surviving Khitan texts are sparse and almost exclusively consist of memorial inscriptions from the Liao state (very few documents in Khitan script survive from the Western Liao); the Jurchens banned the diplomatic and administrative use of Khitan script in 1191 and archival materials from before this date appear not to have survived (219). While relatively few Jurchen texts have survived, their language is much better known than Khitan because Chinese dictionaries of Jurchen and other languages for use by translators and interpreters have survived (the Ming *Hua-Yi yiyu,* surviving in several manuscripts; the vocabularies from the Bureau of Translators list Jurchen characters, while those from the Bureau of Interpreters list only Jurchen pronunciations in Chinese transcription). Although Jurchen script was little used after the end of the Jin dynasty, texts survive from as late as c. 1550; its use was finally banned in 1658 by the Qing dynasty (Kane, 1989: 10).

Khitan and Jurchen texts were collected and studied by Chinese, Japanese, Korean, and Soviet scholars in the first half of the 20th century (particularly Luo Fucheng, Wang Qingju, and Li Dingkui), who made some progress in the decipherment of Khitan script by comparing identical elements of Khitan inscriptions and their Chinese paraphrases, such as names, official titles, and dates; this allowed the identification of some Khitan numerals, animal names, and other words. Real progress in deciphering Khitan script started in 1975 with the foundation of the Khitan Script Research Group of the PRC (principally Chinggeltei, Liu Fengzhu, Chen Naixiong, Yu Baolin, and Xing Fuli). By systematic comparison of the phonetic representation of Chinese names and titles in Khitan texts and from there working out the readings of native words, the readings have been determined for about 208 of 378 known small-script characters and the meanings of over 300 large-script characters (Chinggeltei, 2002: 100–113). Jurchen script was first studied in the West by Wilhelm Grube (1896), with scholarly interest picking up a half-century later. Significant work on Jurchen has been done by Chinggeltei and his colleagues, Jin Qicong, and Daoerji and Hexige (Dorji and Kheshig), with important reconstructions of Jurchen by Kiyose Gisaburo (1977) and Daniel Kane (1989), the latter concerned with spoken Jurchen. The discovery in 1979 of a manuscript dating from shortly after the creation of the script (the *Nüzhen zishu*) has allowed the development of the script to be traced (Kane, 1989: 8).

Khitan and Jurchen scripts look much alike and operate along the same principles. The large scripts were entirely logographic, while the small scripts included phonetic characters. The script was oriented like Chinese; in Khitan, small-script phonetic characters within a word are arranged horizontally in pairs, with the pairs arranged vertically to make triangular or oblong units of as many as seven characters, while Jurchen small-script characters are written sequentially. As Jurchen script developed, it became increasingly phonetic (roughly syllabic); multisyllabic roots written earlier with one logographic character came to be written with all but the first syllable written phonetically, rather like the modern Japanese system of *kanji* and *hiragana*, except that the script makes no rigid distinction between logographic and phonetic characters (Kane, 1989: 28–30). It is unclear whether Khitan script showed a similar development (**Figure 1**).

Tangut (Kychanov, 1995)

The Tanguts, who spoke a Tibeto-Burman language, founded the Xixia (Western Xia) state in modern-day Gansu between 983 and 1038; a Chinese-based script was promulgated in 1037 (Mote, 1999: 180–181). The Tangut rulers heavily patronized Buddhism as a protector of the state and commissioned complete Tangut translations of the Buddhist scriptures (the Tripitaka). In 1210 the Xixia surrendered to Chinggis Khan but refused to fulfill the resulting tributary duties, for which they were destroyed in 1227; the Mongols flattened and burned the Xixia capital Xingqing and killed most of the captives (254–257). This marked the end of most Tangut writing, though its use survived into the 16th century.

Many texts survived in Buddhist temples, including a number of Chinese-Tangut and monolingual Tangut dictionaries and translations of Chinese Buddhist texts and the Chinese classics, first discovered in 1908 by an expedition to Inner Mongolia under Pëtr Kozlov. (The Chinese scholar Zhang Zhu had identified specimens of the by then long-lost Tangut script in 1804, Mote, 1999: 180.) The sources (detailed in van Driem, 1991: 520–523) contain Chinese and Tangut indications of the readings of many Tangut characters (monolingual dictionaries indicate readings with the *fanqie* method), Tangut transliterations of Chinese and Sanskrit words, and Tibetan annotations in a few texts, which have permitted a number of (somewhat inconsistent) partial phonological reconstructions, of which the most important are those of Nishida Tatsuo (1966), Mikhail Sofronov (1968), and Li Fanwen (1986). Nikolai Nevsky carried out important early work on deciphering Tangut before his arrest and execution during the Great Purge of 1937. Tangut morphology and syntax are well understood, particularly through the work of Evgenii Kychanov and Ksenia Keping.

Figure 1 Examples of Khitan and Jurchen scripts (Chinggeltei 107; Kane 21-9).

Tangut script consists of about 6600 square logographic characters written top to bottom and right to left. Because the language was rich in homophones, the principles of Chinese script were easily adapted to it, with characters formed by compounding radicals (determinatives) with simpler characters in several of the ways Chinese characters are formed; however, most of the basic characters do not appear to have a

Figure 2 Tangut script (Keping 90, 330–45).

Chinese source, and, in general, Tangut characters are markedly more complex than Chinese characters (Kychanov, 1995: 228–230) (Figures 2 and 3).

Soghdian Inner Asian Scripts

History and Decipherment

Turkic runiform script (often called 'Turkic runes') and Turkic written in cursive Soghdian script originated during the two Turk empires. The First Turk Empire, founded in 552 by the tribal leader Tumen, was divided into eastern and western halves having distinct economic bases until it fell apart with Chinese connivance in the 580s. While the eastern wing was held together by booty and tribute from China, the western wing relied on tolls from trade along the Silk Road and tribute from the city-states of Central Asia; because of its sedentary character the western half was the source of Turkic scripts. The Second Turk Empire, founded in 683, collapsed in 734 and its remnants were destroyed by the Uighurs in 745.

Figure 3 Samples of Tangut script. (Keping 263; van Driem 529).

Like their predecessors, the Uighurs ruled the steppes through a combination of tribute and booty extracted from the Tang dynasty and international trade until their empire was destroyed in 840 by a revolt of the Kirghiz. Many Uighurs moved south to Central Asia, where in c. 866 they founded a state based on the cities along the Silk Road (Christian, 1998: 252–271). Soghdian merchants, who spoke an Iranian language, dominated trade under all three empires and frequently served as local administrators; from them, dialects of Old Turkic came to be written in a number of related Syriac and Soghdian scripts deriving ultimately from Aramaic, the written language of Achaemenid Persia (253, 257). Runiform script were based on a noncursive script, while Old Uighur was the longest-lived of a family of closely related Turkic scripts based on Soghdian cursive scripts, each generally restricted to a particular religious tradition (particularly Buddhism, Manichaeism, and Nestorian Christianity; see discussion in von Gabain, 1950 [1941]: 15–41). Formerly it was believed that cursive script developed centuries after the creation of runiform script; however, the discovery in the late 1960s of a cursive-script Turkic inscription in Mongolia dated c. 568 showed that the scripts coexisted, with runiform script generally filling a secular role.

Mongolian script was taken over almost unchanged from Old Uighur script, probably as early as 1204 (Christian, 1998: 398–399; Mote, 1999: 424). The Uighurs became the first sedentary people to submit to Chinggis Khan in 1209, and by loyally fulfilling their tribute obligations they soon came to constitute the core of the Mongol administration in conquered sedentary states; they wrote Middle Mongolia with Old Uighur conventions. A number of scripts for Mongolian were devised under Tibetan influence in the 16th century (the 'horizontal square script' and the *svayambhu* or *soyombo* script) but found mostly ceremonial uses. A variant called 'clear script' (Mong. *toda üsüg*, Oirat *todorxoi üzüq*) was devised in 1648 by the lama Zaya Pandita Ogtorguin Dalai to eliminate the ambiguities of Mongolian script and found official use in Dzungaria, the state founded by the Oirats (the westernmost branch of Mongols); it was used by the Kalmyks (western Oirats) until the 1920s and remains in use in parts of Chinese Turkestan (Kara, 1996: 548–550). Apart from these and 'Phags-pa script, Mongolian script continued to be used by most groups of Mongols until the tripartite division of ethnic Mongolia in the 20th century: Buriat, the group of Mongolian dialects spoken on Russian territory, was cyrillized in 1939; Outer Mongolia (predominantly Khalkha) broke away from China in 1911 and abandoned Mongolian script under Soviet pressure in the early 1940s, although the republic has introduced and repeatedly

postponed plans to make Mongolian script official since 1990; to this day, Mongolian script serves as a pan-dialectal writing system in Inner Mongolia. (There were also unsuccessful latinizations of Buriat and Khalkha in the 1930s.)

The Manchus conquered the eastern or Khalkha Mongols in 1636 and North China eight years later, founding the Qing dynasty of China. The founder of the Manchu state, Nurhaci, had established a Manchu script in 1599 closely based on Mongolian. Remaining ambiguities were removed in 1632 by introducing certain diacritical marks ('script with circles and dots,' or *tongki fuka sindaha hergen*); this script is often considered the most esthetically pleasing of the Inner Asian Soghdian scripts. Manchu served as the language of high Manchu officials of the Qing dynasty until its fall in 1911, though most Manchus were native speakers of Chinese at least a century and a half before. Manchu script was also used to write the Manchurian languages Daur (Mongolic) and Evenki (Tungusic). Slightly modified Manchu script is currently used to write the Sibo (Chin. *Xibe*) dialect of Manchu, spoken in Xinjiang by descendants of Manchu border garrison tribes.

Western scholars knew of runiform inscriptions of southern Siberia (the 'Yenisei inscriptions,' written in Old Kirghiz) by the 1730s with the publication of Philipp Johann von Strahlenberg's account of his travels (1738); however, they were not systematically collected until two Russian expeditions of 1887 and 1888 led by Wilhelm Radloff (1892), shortly followed by Nikolai Yadrintsev's discovery of the first 'Orkhon inscriptions' in the Orkhon Valley of Mongolia in 1889. Each of the first two Orkhon inscriptions, the Köl Tegin (732) and Bilgä Kagan (735) inscriptions, covers three faces of a monolith, with a parallel Chinese inscription on the western faces. The fact that the language of the inscriptions was identified greatly eased their decipherment, which was announced by Vilhelm Thomsen in 1893 and published in 1896, with refinements during the next 50 years. Besides three other major and several minor Orkhon inscriptions from the second Türk empire and the Yenisei inscriptions, there are three inscriptions in Mongolia from the Uighur empire and several manuscripts in runiform script from Turkestan (particularly the *Ïrq Bitig*, or *Book of Divinations*). There are numerous inscriptions in a runiform script from Khazaria (630–965), an offshoot of the second Turk empire based north of the Caucasus, that are unrelated and remain largely undeciphered. Western knowledge of Mongolian and of classical script started in earnest with the research of Peter Simon Pallas (1769–1774), Józef Szczepan Kowalewski (1844–1849), and Aleksei Bobrovnikov (1849).

Principles of the Scripts

The Soghdian scripts used to write varieties of Old Turkic had three vowel signs and a surplus of consonant signs. Because Old Turkic had eight phonemic vowels, unmodified Soghdian script could not indicate vowel harmony unambiguously. The dearth of vowel signs was made good by indicating the vowel harmony of a word by the choice of consonant signs. Ideally, all consonants would have had separate signs for front-vowel and back-vowel words, but in practice many consonant signs were neutral.

Turkic Runiform Script (von Gabain, 1950 (1941); Tekin, 1968; Kara, 1996)

Monumental runiform script typically runs right to left, with rows read from bottom to top; the orientation is more varied in other sources. Two vertical dots are used to separate words. The runiform script used in the Orkhon inscriptions contains 40 signs; some supplemental and variant forms occur in other texts. Four signs indicate vowels without a following consonant, and another 27 can indicate either a consonant or a sequence *aC/äC/eC*, 20 of which indicate vowel harmony. Of the remainder, three indicate consonant clusters with preceding *a/ä*, two a velar consonant preceded or followed by a rounded vowel, and four miscellaneous sequences.

Texts vary in the extent to which vowels inside a word are written, with manuscripts approaching alphabetic writing and inscriptions more underspecified. When marked, vowel length is indicated by an extra vowel sign; for example, the negative existential verb *yōq* 'there is not' is written y^1-*u*-*oq*, where the long vowel is confirmed by, for example, the diphthong in Yakut *suoχ* 'id.' (Tekin, 1968: 52). In the Orkhon inscriptions, the treatment of vowels depends on their position in the word, with vowels in first syllables marked much more often than in later syllables (Figures 4 and 5).

First syllable: In vowel-initial words, short *a/ä/e* are not marked, being inherent in the following consonant sign, while their long counterparts are frequently written. Other initial vowels are always written. Non-initial *a/ä/e* are usually not marked, long or short; *i/ï* are frequently though not systematically marked; rounded vowels are almost always marked. (The mid-rounded vowels *o/ö* only occurred in the first syllable in this stage of Turkic.)

[a]Transcribed C^1 for back vowel words, C^2 for front vowel words, except for velars.

[b]Neutral consonant signs indicate *aC/äC/C*, back or front signs *aC/C* and *äC/C*, resp.; special velar signs can have a rounded vowel either preceding or following the consonant.

Figure 4 Runiform script. (Radloff 2; von Gabain 12; Tekin 23–4.)

Later syllables: Most medial short vowels are not regularly marked, except for *u/ü* following a syllable with an unrounded vowel. Long medial vowels tend to be marked, *i/ï* usually and the others sporadically. Word-final vowels are always marked. (Tekin, 1968: 30–38)

Cursive Soghdian-Based Scripts

Cursive-script Turkic was originally written from right to left, with rows running top to bottom, but under Chinese influence was rotated 90 degrees to run top to bottom and left to right, which is the orientation of Mongolian and Manchu scripts. As the name implies, words were written as sequences of distinctive signs strung along a vertical spine and were separated by uniform spaces, with major syntactic units separated by a variety of groups of dots (one or two dots separating clauses, for example, and often four dots in a diamond separating paragraph-level units). In cursive scripts vowels were always written (Figures 6 and 7).

There are three orthographic principles common to the three cursive scripts. First, the scripts distinguish initial, medial, and final forms of letters; a limited set of separate forms could occur word-finally to break up certain ambiguous sequences of signs. Positional variants serve to mark morpheme or word boundaries: all verbal suffixes are written joined to the stem, but noun roots frequently end in final forms, separated by a space from suffixes beginning with initial or medial forms; this juncture is transcribed with a hyphen. Pronominal forms, which unlike nouns have extensive allomorphy, are regularly written as a unit, as are words in other classes; in particular, inflected noun forms with special adverbial meanings are usually written as a unit (e.g., Manchu *dade* 'in the beginning', a specialized sense of the dative/locative of *da* 'root').

Second, as in runiform script, cursive scripts indicate vowel harmony by the choice of certain consonant signs; vowel signs are underspecified. Old Uighur (with nine vowels) and Mongolian (with seven) used the three Soghdian vowel signs as follows. *Aleph* and *yodh* were used to write the vowels *a/ä* and *i/ï/e* in Old Uighur, respectively, and *a/e* and *i* in Mongolian. In first syllables *waw* indicated *o* or *u*, the ligature *waw* + *yodh* either *ö* or *ü*, while in later syllables *waw* was used for all four rounded vowels. (*o* and *ö* occurred only in initial syllables in Middle Mongolian and only rarely in noninitial syllables in Old Uighur.) All word-initial vowels except *e* were preceded by an *aleph* written with a special sweep, called *titem* (from Greek *diadem* 'crown'). For the most part, vowel harmony was indicated by the signs used for velar consonants, with Aramaic velar and uvular signs being used in front- and back-vowel words, respectively. Apart from the word-initial distinction between *a* and *ä/e*, there were no other indications of vowel harmony in Old Uighur or Mongolian; in Manchu, signs for dental stops also indicated vowel harmony. Most long vowels could be indicated in Old Uighur script by duplicating *yodh* or *waw*, though frequently this was not done;

'Because the lords and the people were discordant, because the Chinese were deceitful and crafty, because younger and older brothers created rifts, and because the lords and the people slandered each other, the Türks lost the nation they had founded, they lost the emperors they had set up. For the Chinese people their noble sons became slaves, their highborn daughters became concubines; the Türk lords lost their Türk names. The lords in Chinese lands kept their names and submitted to the Chinese emperor, and for fifty years gave them labor and strength.'

Figure 5 Sample of Turkic Runiform script. Lines 6–8 of the east side of the Köl Tegin inscription, describing the fall of the first Türk empire as seen by the rulers of the second. Front-vowel signs indicated with bold type. (Radloff 7; Tekin 233; von Gabain 250.)

this practice was not carried over into Mongolian (except in transcriptions of Sanskrit), which, unlike the modern dialects, seems not to have had distinctive vowel length, and was reintroduced only for *waw* in Manchu script to distinguish certain homophones.

Finally, all three languages were written as having CV(C) syllable structure, which rendered the 'tooth letters' *aleph*, *nun*, and *gimel/heth* ambiguous. The latter two were given distinct syllable-initial and syllable-final forms by the addition of diacritical marks. The only syllables in Old Turkic and Middle Mongolian that did not fit this rule were those containing diphthongs of the form $V+y$, which were written as two syllables, *ayi*, etc., except word-finally (and in Mong. *naiman* 'eight') as *-ai*. However, Manchu also allowed the onsets *y* and *w* and the offglide *w*; the onsets were written as sequences *ow* and *iy*, and the offglide *w* as *o*: *niyowanggiyan*

Figure 6 Old Uighur script. (von Gabain 17–25; Kara 540.)

[ɲ^{w}aŋg^{y}an] 'green', *deo* 'younger brother', and note doublets like *goimbi/gûwaimbi* 'to hit the target'.

Ambiguities of Mongolian Script

Besides Old Uighur ambiguities in writing rounded vowels, several differences in the phonologies of the two languages led to ambiguities in Mongolian script. First, the only consonants that could occur word-initially in Old Uighur were *b, t, k, č, s, y,* and (rarely) *m* and *n* (von Gabain, 1950 [1941]: 52); thus, Mongolian script did not distinguish the voicing of word-initial stops. Second, Old Uighur script did not distinguish between *k* and *g* in front-vowel words

---

[1] In Old Turkic, numbers in the decades take the form *unit* + *succeeding decade*.

[2] Past converb: Action precedes that of the following verb.

[3] In Old Turkic, the 3s pronoun *ol* 'he, she, it; that' also served as a copula.

Figure 8 Mongolian script (Kara 545–8).

and, as time passed, lost a strict graphical distinction between medial *d* and *t*; thus the voicing of most stops is ambiguous in Mongolian script. (This ambiguity was somewhat reduced because Middle Mongolian did not have *p* or syllable-final voiceless obstruents.) Third, because Old Uighur did not have *j*, it was written with the sign for *y* word-initially and (after the 17th century) with an alternate form of *č* medially; a distinct form for initial *y* was borrowed from Manchu script in the 19th century. Finally, Middle Mongolian possessed word-initial *h* (lost fairly early) that was not written. A number of devices served to reduce some of the resulting ambiguity: for example, some important homophones were disambiguated by

'[You,] my dear aunt, living on the Onon River, and / [I], the sick one, who lives on the Orkhon and Tula—we two, / although the lands of the Khalkha and the Ongnuut are far apart, / are one in the sphere of mutual love and longing. // If we do not meet again in this life, / then in all our future lives, / as a mother loves her only child, / let us help each other in every way (by all means).'

Figure 9 Sample of Mongolian script. The 6th and the 7th quatrains of a poem of Prince Tsoght of the Khalkha (1621) addressed to his paternal aunt. The language of the poem shows a number of modern features, such as *o* and *ö* in non-initial syllables. The text is reproduced from Vladimirtsov with slight changes to better resemble the original. The numbers in the text refer to the lines of the inscription; each quatrain is numbered in Tibeto-Mongolian numerals, left out in this transcription. (Vladimirtsov 1253–1280.)

ad hoc spellings, such as *yesün* in place of *yisün* 'nine' to prevent confusion with *jisün* 'complexion', and *waw* was written double following a velar stop to indicate the value *g*, with *k* indicated by a single *waw* (Sanzheyev, 1988 [1964]: 34–35). On the whole, however, Mongolian tolerated extensive ambiguity (Figures 8 and 9).

Manchu Script Reforms

After the reform of 1632, Manchu script had two additional diacritics and three additional consonant signs (for *p*, *f*, and initial *y*), which eliminated all ambiguities. This was possible because Manchu had only five vowels and much-reduced vowel

[a]Takes dot if necessary to prevent ambiguity. e.g., *aǰi* 'firstborn' vs. *enǰi* 'vegetarian' (adj.)'
[b]Except following labial and front-velar signs.
[c]Rare except in foreign words.
[d]Also has separate form for genitive marker *-i*.

[a]Only the voiceless stops occur in this position.
[b]Also followed by *i*. (Convention for Mandarin.)

[a]Indicates *f* before *i*, *o*, and *u*, *w* before *a* and *e*.
[b]Indicates *f* before *a* and *e*.
[c]Only in foreign words.
[d]Dot omitted in syllable-final position.
[e]Takes dot in certain Chinese words.

Ligatures with *p* are formed like those with *b*. Diacritics for *g* or h are written to the right of the curve of the *k*.

Figure 10 Manchu script (Kara 550–4).

The Manchu system is similar to *pinyin* but is based on an older form of Mandarin. Tone is not marked. Initial consonants are generally written with the corresponding Manchu signs (voiceless for aspirated, voiced for unaspirated), with additional signs for back velars, certain affricates, and *r*. Back velars are written with a modified form of the front-velar sign, with voicing and frication shown by the circle and dot; *k* and *g* are usually written with this sign, but *h* is quite often written with the usual back-velar sign. (*Pinyin* is indicated by italics, Manchu spellings by boldface.)

c (**ts**) *k* (**k'**) *zu* (**dzu**)
z (**dz**) *r* (**ž**)

Between an initial consonant and the vowel Mandarin allows the three glides written *u, i*, and *ü/u*. The first two are written **-iy-** and **-uw-/-ûw-**; the last will be discussed presently. Vowel-coda combinations are written as in *pinyin* (for example, *eng* as **eng**), with these exceptions: *ou, ao, ong,* and *(u)o* are written **eo**, **ao/oo**, **ung/ûng**, and **o**, respectively.

meng (**meng**) *long* (**lung**) *lian* (**liyan**) *hua* (**hûwa**)

Unlike *pinyin*, Manchu uses the same symbol for palatal and retroflex affricates, with a following **i** to indicate the former. Thus, *chan* is written **čan**, while *qian* is **čiyan** or **kiyan**. On the other hand, the retroflex fricative *sh* is written **š**, with the palatal fricative *x* written **si** or **hi**. Syllables of the form *jiong* and *jiu* are usually written **jiong** and **jio**, but **-iyung** and **-iyu** also occur.

xiao (**hiyoo**) *Jiangxi* (**giyangsi**)

There are special conventions for writing the final retroflex glides in *zhi, ri*, etc.

ci (**tsï**) *zi* (**dzi**) *si* (**sï**) *ri* (**ži**)

chi (**či**) *zhi* (**jï**) *shi* (**ši**)

The consonants *q, j, x, l*, and *n* can be followed by the glide *ü* (written *yu* initially) and the vowel *ü*. The most common ways of writing these syllables are as for *j-*.

ju **jioi** *juan* **jiowan** *jue* **jiyo** *jun* **jiyûn** *nü* (**nioi**)

The most common variants are **yuwan** and **yuwei** for *yuan* and *yue*, and **ji(y)owei** and **jiyuwei** for *jue*; *xun* and *yun* often have **u** for **û**. (*q, j,* and *x* are also often written **k**, **g**, and **h**.) Finally, note the following spellings.

fen	**fen/fun**	*you*	**io**
feng	**feng/fung**	*wo*	**o**
fu	**fu/feo**	*wu*	**u**
lun	**luwen**	*er/-r*	**el/-l**

[1] *gelhûn-akû* followed by a negative verb is an idiom for "not to dare to *verb*."
[2] Literal term for "daughter," also used to mean "young woman."
[3] *čib* is sound-symbolic for great quiet; *se-me* is the imperfective converb of *sembi* "to say." Phonesthetic adverbial constructions in *seme* are very common in Manchu.

'When he turned his head to look the maiden in falling braids walked past smiling happily. He followed her immediately. Passing a curved railing she went into a small house. Embarrassed, he hesitated and did not dare advance. The young woman turned her head and offered him the flower she held in her hand. Because she had made a sign beckoning him from afar, he rushed into the house. It was quiet and no one else was around, and when he advanced and embraced her she offered no resistance at all. Then, trembling together, they fell in love.'

Figure 12 Sample of Manchu script. From a mid-Qing woodblock print of the Manchu translation of "Painted Wall," from Pu Songling's *Liaozhai Zhiyi* (*Strange tales from a make-do-studio*). (Pu 59–60.)

harmony (*e* alternated with *a* and *o*; *i* and *u* were neutral, as were many suffixes with *e*). The two diacritical marks were a small circle and a small dot added just to the right of the consonant sign or the following vowel sign. The first was affixed to velar stop signs to indicate *h* (/x/). The second served to indicate two distinct features depending on the place of articulation of the consonant. For velar and dental stops, the dot indicated voicing, with distinct forms of the consonant signs to indicate vowel harmony. For other consonant signs (and for word-initial *u*), the dot indicated the higher vowel of the pairs *a/e* and *o/u*. While dental signs followed by *u* did not indicate the vowel harmony of a word, velar signs did; to prevent the ambiguity that would have resulted between *go* and *ku*, the ligature *waw* + *yodh* (transcribed *û*) indicated *u* following velars in back-vowel words. This ligature was used sporadically in other environments, apparently in many cases to distinguish (near) homophones: *tumbi* 'to hunt' vs. *tûmbi* 'to hit, beat, pound', *munggan* 'tumulus; mausoleum' vs. *mûnggu* 'bird's nest'; a few words show both forms: *šungge* ~ *šûngge* 'learned; fine-grained'. Manchu also developed a system for transcribing Mandarin (**Figures 10–12**).

Aspect and Aktionsart

H-J Sasse, University of Cologne, Cologne, Germany

Phases and Boundaries

The notions of 'aspect' (also called 'viewpoint' or 'perspective') and 'aktionsart' (also called 'lexical aspect,' 'aspectual class,' 'aspectual character,' 'actionality,' 'situation type' as well as a few other terms) are concerned with the temporal semantics of an utterance in terms of the time intervals (also termed 'phases') conceptualized in the construal of the situation expressed by that utterance. The fundamental criterion is the inclusion or noninclusion of starting points and/or end-points ('boundaries') in the conceptualization of the situation. In a sequence of utterances such as the following, a number of different types of situation boundaries are involved: *Yesterday we went to the beach. We knew the weather was fine. My son built a sand castle, then we swam for half an hour, and then we went home*.

The predicate of the first clause, *went to the beach*, may be said to be associated with at least three different types of boundedness on three different levels of representation. First, it is bounded by virtue of it being one link in a chain of narrated events which happen in a temporal sequence, each event bounding the preceding and the following one (*x* and then *y* and then *z*). This type of bounding will not concern us at the moment. Second, on the abstract lexical-semantic level, the event {go to the beach} has a built-in goal, the location *beach*, which terminates the event when reached. This is a different type of boundedness, embedded in the semantics of the expression (constructional semantics plus the lexical semantics of the constituent parts of the construction). Third, the simple past *went* (as opposed to the progressive *were going*) suggests that the goal is actually reached. This provides us with the third level of bounding, the actual temporal marking at the utterance level, which spells out the intrinsic bounding, already prepared, as it were, by the presence of the directional locative phrase.

In the mainstream of both classical and modern aspectology, the third type of bounding, the act of completing the event, indicated by means of the simple past, would be regarded as a matter of aspect, while the second type of boundedness, the intrinsic one, would be regarded as a matter of aktionsart. As our little example shows, the act of realizing inherent boundedness at the utterance level is performed in English by the aspectual values of the tense morphemes, which act as aspect operators ('aspect grams'). Had we said *we were going to the beach*, this would imply that the end-point was not yet reached: we were still on our way, that is, in the preliminary phase (henceforth pre-phase) of going to the beach. Thus, one may say that the abstract phrase *go + definite directional* is semantically designated for an end-point, but is (at the abstract lexical-semantic level) underspecified for the actual realization of this end-point. There are two formally distinct 'tenses' in English that regulate the choice between the pre-phase interpretation and the interpretation of the end-point being actually reached: the simple past and the progressive. In traditional terms the simple past would be considered as an instance of the perfective aspect (boundary indicating), and the progressive as an instance of the imperfective aspect (non-boundary indicating). The aktionsart under discussion here is called telic (Greek 'having an inherent goal/end-point'). Telic events fall into several subtypes depending on how much pre-phase they admit; the type we are concerned with here and which allows for a fairly separate activity phase is called accomplishments, in contrast to achievements, such as *reach* or *die*, which allow for very little if any pre-phase (on aktionsart terminology see below).

Aktionsart is traditionally defined as a lexically inherent semantic property of the simple verb, characterizing the phasal time structure of the event it denotes, i.e., the various intervals of its development (beginning, end, repetition, etc.). As we see here, this traditional view is misleading. Aktionsart is actually a property of the verb plus its argument frame. Thus, several distinct frames may lead to the same aktionsart interpretation, and quantificational or determinational features of arguments in the same frame may lead to different aktionsart interpretations, both independent of the verb's 'basic' aktionsart. While in the example discussed above the built-in end-point of the telic accomplishment predicate is a directional, in the third clause of our little story it is an object (*a sand castle*) that is created by the activity expressed by the verb; once the object is ready, the situation has reached its natural goal. The implications of the simple past and the progressive are the same as in the first example: *he built a sand castle* suggests that the sand castle is finished, while *he was building a sand castle* suggests that he was in the pre-phase of building it. The end-point may also be completely inherent in a simple verb, as in *turn*: if we say *he was turning* he hasn't completed the turn, but if we say *he turned*, the turn is done. As for quantificational features that may come into play, {build a sand castle} is a telic event, while {build

sand castles} is not: the bare plural does not suggest a limited number of sand castles that would naturally terminate the event when ready.

In our little story, we have a simple predicate of this kind: *swim* in the third sentence. This verb is atelic: it does not have a built-in end-point. Boundedness here comes about through the durative time adverbial *for half an hour*, which sets a time frame with a clear end-point. However, this end-point is different from that established by the spatial goal or the completed entity in the first two clauses. This finds its linguistic correlate in the fact that one cannot say *we were swimming for half an hour* implying that we were in a pre-phase of completing the 30 minutes. This state of affairs is characteristic of a class of verbal expressions whose aktionsart value is called activities. These are characterized by the fact that they do not have natural end-points but, rather, arbitrary time limits. One cannot swim for eternity: at one time, one starts doing it, and after a while, one stops. Here, the contrast between simple past and progressive has quite different implications. The simple past *we swam* indicates that the entire act, including its beginning, its active phase, and its end, happened at a certain time in the past. The progressive *we were swimming* indicates that only the active (ongoing) phase is described, while the arbitrary beginning and end-point are out of focus; they are not implied by the grammatical form.

Let us finally look at the verb *know* in the second sentence. It is clear without further consideration that the situation expressed in this sentence is not bounded by the surrounding events. We probably already knew that the weather was fine before we started to go, and nothing is implied about when we learned of it; likewise, nothing is implied about whether or when we will stop knowing it. In fact, no boundaries are conceptualized here at all. This is characteristic of the aktionsart called states. The same form (simple past) is used here as with the complete, boundary-including phase of activities, but in a different reading: since no boundaries are implied, it pertains to the persistent state of knowing in the past. The progressive is not compatible with this aktionsart.

In summary, each aktionsart has its characteristic pattern involving two types of information concerning the aspect operators (aspect grams): co-occurrence restrictions between aktionsart and aspect operators, and the semantic effects induced by a certain aktionsart for the aspect operators. Aspect systems in the languages of the world are typically characterized by this kind of interaction between the two dimensions of aktionsart and grammatical aspect, which is manifested in the interplay of different temporal bounding or unbounding characteristics: those inherent in the aktionsart, which are part of its semantics, and those provided by grammatical aspectual devices such as the progressive/simple past distinction in English. The details of this interplay are a matter of the individual language's lexicogrammar, whose organization in terms of verbal semantics and inventory of grammatical devices sets the stage for the actual phenomenon of interlocking between these two dimensions.

Aspect Theories and Their Historical Development

An excellent introduction to the early history of aspectology is found in Pollak (1988). The grammatical description of the Slavic verb system served both as an instigator and as a pacemaker for later developments of the theory. The first descriptions of aspectual oppositions in Slavic languages go back to the early 17th century. The Prague scholar Benedikt von Nudožer was the first to describe grammatical aspect as a complementary system of two perspectives or viewpoints, which later came to be called perfective and imperfective (these are loan translations of Russian *sovershennyi vid* 'completed viewpoint' and *nesovershennyi vid* 'uncompleted viewpoint' respectively). The Russian term *vid* 'viewpoint', which provided the basis for the loan translation 'aspect,' was first used by N. I. Greč in his Russian grammar of 1827. These early works shaped the concept of a system of 'aspects' or 'aktionsarten' (the terms being used synonymously by that time) of roughly the following form: the speaker has a choice between two options: he may present a situation as an undivided whole, including both its initial and final boundaries (perfective); or he may present a situation from an internal perspective, ignoring the boundaries of a situation (imperfective). This concept was then applied by Indo-Europeanists to morphological oppositions in other languages where a similar semantic distinction was found, such as Greek aorist versus imperfect, Latin perfect versus imperfect, French *passé simple* versus *imparfait*, English simple past versus progressive past, etc.

The first attempt to differentiate between grammatical aspect and the lexically inherent time-constitutional characteristics of verbs was Agrell (1908), which exploited, for that purpose, the presence of the competing synonymous terms 'aspect' and 'aktionsart' by distinguishing them in much the same manner as we do today. His main point was that grammatical aspect cuts across aktionsarten, e.g., the imperfective aspect is compatible with the nondurative aktionsart (durative versus nondurative was the terminological predecessor of what was later called atelic versus telic), thus showing that one needs two

dimensions to deal with the whole range of phenomena. Even though this convinced many scholars in the first half of the 20th century of the necessity to differentiate between grammatical aspect and lexical aktionsarten, the aktionsart theory enjoyed limited success, perhaps due to the fact that aktionsarten continued to be defined as formal, i.e., derivational categories. The classic Slavist aktionsart terminology as we still find it today in handbooks of Russian and other Slavic languages (e.g., ingressive [beginning of action], egressive [end of action], delimitative [a certain temporal extension], iterative [repetition or habituality], semelfactive [single instance]) is all associated with certain derivational devices, mostly verb prefixes, occasionally also suffixes. The situation was further complicated by the oddities of the Slavic system with its enormous overlap in the formal devices used to mark grammatical aspect and aktionsarten. Attempts at a proper systematization of phasal time constitution and its interrelation with grammatical aspect operators (grams) was thus hampered by the presence of two independent approaches: a logical/philosophical one where aktionsarten were taken to be abstract schemata characterizing all predicate expressions, and a morphologically oriented one that defined aktionsarten in terms of derivational morphology, ignoring the question of how the simplex, nonderived items would fit into an overall schema of time constitution. (For a brief characterization of the situation in the early 1980s see Krifka, 1989: 102–106.) Under these circumstances, research on aktionsarten would possibly have come to a dead end, were it not for the fact that Zeno Vendler's famous 'time schemata' of 1957 (better known in the version of 1967 and extremely influential since then) brought a breath of fresh air into attempts at coming to grips with aktionsart semantics. Not originally intending to provide a classification of lexical verbs (this was often misunderstood because of his use of the term 'verb'), Vendler divides the universe of 'verbs' into four 'time schemata': activity terms, accomplishment terms, achievement terms, and state terms. The first two make up a class of processes, consisting of successive phases and allowing the use of the progressive in English. Activities and accomplishments are distinguished by the fact that activity terms are atelic ('do not have a set terminal point'), while accomplishment terms are telic and share this feature with achievements. Chief criterion for telicity is the compatibility with durative time adverbials (*for an hour*) and frame adverbials (*in an hour*); activities are compatible with the former, but not with the latter, while the reverse is true for accomplishments. Vendler's standard examples show that he does not classify lexical verbs in the sense of the classic aktionsart approach but uses actual verb phrases:

Activities:	run, push a cart
Accomplishments:	run a mile, draw a circle, grow up
Achievements:	win a race, reach the summit
States:	love somebody, have something

The time schema approach had a great impact on research into aspect and time constitution in formal grammar and early computational linguistics, mainly because of its refinement by David Dowty (Dowty, 1979). The post-Vendlerian approach splits aspectologists into two groups, which I have termed 'unidimensionalists' and 'multidimensionalists' (Sasse, 2002). The unidimensional approach proceeds from the assumption that aspect and aktionsart are essentially the same phenomenon (predominantly called 'aspect' in these approaches). What traditional aspectology would have analyzed as the interaction between the two is usually treated as 'recategorization' in an unidimensional approach, e.g., the progressive aspect in English used with a telic verb as in *he's dying* could be looked upon as an achievement recategorized as an activity. This approach is inadequate as it does not allow a proper treatment of the subtle semantic nuances that arise from the interaction between lexical aktionsart characteristics of verbs and verb phrases on the one hand and the semantics of aspectual markers in languages with richer grammatical aspect systems on the other. Moreover, the affinities between perfectivity and telicity on the one hand, and imperfectivity and nontelicity on the other, leave one type of interaction unaccounted for, namely activities, which are typically characterized by their compatibility with both perfectivity and imperfectivity. Nevertheless, important work in particular on the compositionality of the aspectual interpretation of sentences (i.e., the influence of quantificational and determinational characteristics of noun phrases involved – cf. the examples in the previous section) has been done by unidimensionalists. A different approach to these issues on the basis of a multidimensional understanding of aspect and aktionsart was taken by Krifka (1989).

In multidimensional approaches, two levels are assumed: one of lexical aktionsart, and one of grammatical aspect, the latter interacting with the former. How this might work was informally demonstrated in the previous section. There are several variants of this approach. A 'selection theory' would assume every aktionsart to have a characteristic interaction pattern for the aspect categories, resulting in 'interaction senses'; both the perfective and the imperfective aspect would have a number of specific

'readings,' depending on the interaction with the aktionsart they combine with. A 'cumulative theory' would assume total independence, resulting in the cumulation of aktionsarten and aspect semantics. It seems that the unidimensional approach is gradually losing ground. Modern aspectology is characterized by numerous different multidimensional approaches, where aktionsart systems of various sizes are proposed, all elaborating on the Vendler categories, as we did in the previous section (cf. Breu, 1994; Bertinetto, 1997; Smith, 1997). An excellent table comparing some of these systems is found in Tatevosov (2002: 320–321); see also Sasse (2002).

Plato in such works as *Cratylus* takes a sentence to be a series of names. This view is untenable because it is not the case that in uttering a series of names one thereby says something either true or false. "Ephesus, 483, Neptune" says nothing either true or false. By contrast, an indicative sentence, such as "Ephesus was a large city," is true, and it seems to include elements other than names. Aristotle seems to be making just this point when in *De Interpretatione* he remarks

> Falsity and truth have to do with combination and separation. Thus, names and verbs by themselves—for instance "man" or "white" when nothing further is added—are like the thoughts that are without combination and separation. So far they are neither true nor false (1963: 16^a9)

Aristotle, however, does not distinguish in his use of "statement" among (1) the sentence used to express a proposition, (2) the proposition thereby expressed, or (3) the use of that proposition in the performance of a speech act, such as an assertion. These are three distinct phenomena, but it took over two millennia before the point was formulated clearly by the philosopher-logician Gottlob Frege.

According to Frege, a proposition (such as the proposition that global warming is accelerating) is an abstract object, the existence of which does not depend upon any mind grasping it or any sentence expressing it (1984). By contrast, a sentence expresses a proposition if it is indicative and meaningful. Unlike propositions, sentences exist only as part of a conventional linguistic system and so in a clear sense depend upon human activities. Nevertheless, one can utter a sentence expressing a proposition without making an assertion. One might utter such a sentence in the course of testing a microphone, or in rehearsing one's lines for a play, or for that matter in

'readings,' depending on the interaction with the aktionsart they combine with. A 'cumulative theory' would assume total independence, resulting in the cumulation of aktionsarten and aspect semantics. It seems that the unidimensional approach is gradually losing ground. Modern aspectology is characterized by numerous different multidimensional approaches, where aktionsart systems of various sizes are proposed, all elaborating on the Vendler categories, as we did in the previous section (cf. Breu, 1994; Bertinetto, 1997; Smith, 1997). An excellent table comparing some of these systems is found in Tatevosov (2002: 320–321); see also Sasse (2002).

Plato in such works as *Cratylus* takes a sentence to be a series of names. This view is untenable because it is not the case that in uttering a series of names one thereby says something either true or false. "Ephesus, 483, Neptune" says nothing either true or false. By contrast, an indicative sentence, such as "Ephesus was a large city," is true, and it seems to include elements other than names. Aristotle seems to be making just this point when in *De Interpretatione* he remarks

> Falsity and truth have to do with combination and separation. Thus, names and verbs by themselves—for instance "man" or "white" when nothing further is added—are like the thoughts that are without combination and separation. So far they are neither true nor false (1963: $16^{a}9$)

Aristotle, however, does not distinguish in his use of "statement" among (1) the sentence used to express a proposition, (2) the proposition thereby expressed, or (3) the use of that proposition in the performance of a speech act, such as an assertion. These are three distinct phenomena, but it took over two millennia before the point was formulated clearly by the philosopher-logician Gottlob Frege.

According to Frege, a proposition (such as the proposition that global warming is accelerating) is an abstract object, the existence of which does not depend upon any mind grasping it or any sentence expressing it (1984). By contrast, a sentence expresses a proposition if it is indicative and meaningful. Unlike propositions, sentences exist only as part of a conventional linguistic system and so in a clear sense depend upon human activities. Nevertheless, one can utter a sentence expressing a proposition without making an assertion. One might utter such a sentence in the course of testing a microphone, or in rehearsing one's lines for a play, or for that matter in

investigating a proposition to see what its consequences are without endorsing it. For instance, one might put forth the proposition that global warming will cause the melting of Greenland's glaciers to see what would follow (the submersion of Florida, etc.) without claiming that global warming will in fact go so far as to melt Greenland's glaciers.

There are three distinct items then: an indicative sentence, a proposition expressed by that sentence, and the use of that sentence and proposition expressed to make an assertion. 'Statement,' 'claim,' 'judgment,' and even 'proposition' are often used interchangeably among these three notions, and in the history of philosophy no small amount of mischief has resulted from such ambiguous usage. (For a trenchant discussion of such ambiguity, see Geach, 1972; on the distinction between illocutionary force and semantic content, see Green, 2000.)

Isolating assertions from propositions and indicative sentences is only the beginning of wisdom about the former. An assertion is a speech act. Just as one can make a promise by saying, "I promise to do so and so," so too one can assert P with such words as "I hereby assert that P." (Austin, 1962 placed assertion on his list of 'expositives'; Vanderveken, 1990 locates assertion on his list of 'assertives.') Further, just as a promise can only be made if certain conditions have been met (you cannot promise to do what is obviously outside your control), so too an assertion can only be made under certain conditions. For instance, it is doubtful that you can assert what is obvious to both you and your audience to be false. An attempt to do so will most likely be taken facetiously. Further, Strawson (1950) held that a sentence can make presuppositions that if not met prevent that sentence from being usable for assertions. If Iceland has no monarchy, then according to Strawson my utterance of, "The present queen of Iceland is beautiful," will fail to make an assertion in spite of the fact that I have in good faith uttered a meaningful indicative sentence.

To assert a proposition is at the very least to put it forth as true. Searle (1969) tried to capture this dimension by construing an assertion of proposition P as an "undertaking to the effect that P." That may be a necessary, but is not a sufficient condition: My betting a large sum on P's coming out true is an undertaking to the effect that P is true, but it is no assertion thereof. (For instance, if I bet on P without believing P true, I am not a liar; if I assert P under those conditions, I am.) Searle, however, elsewhere wrote that an assertion has word-to-world direction of fit. According to this conception, inherent in the practice of asserting is the norm that the speaker's words are supposed to track how things are. This feature distinguishes assertion from, say, commands, the aim of which is not to track the world but rather to get the world (in particular, one or more of its inhabitants) to conform to what the command enjoins. Commands are thus commonly said to have world-to-word direction of fit.

This notion of word-to-world direction of fit may be elaborated further by the way in which one sticks one's neck out by making an assertion. One who asserts a proposition P is right or wrong on the issue of P, depending upon whether P is true: one is right on that issue if P is indeed the case and wrong if it is not. In thus exposing oneself to liability to error on the issue of P, one is doing more than if one had just uttered a sentence expressing P.

However, liability to error on the issue of a particular proposition still does not distinguish assertion from other speech acts involving propositions. One who guesses that P is also right or wrong on the issue of P, depending on whether P is the case. How may we distinguish assertion from other proposition-involving speech acts? Williamson (1996) contended that one who asserts P is thereby open to the challenge, "How do you know?" This much may not be said of other proposition-involving speech acts. For instance, it would be inappropriate to respond to one who conjectures, guesses, or supposes for the sake of argument that a black hole inhabits the center of the Milky Way, with the question, "How do you know?" Unlike these other speech acts, an assertion purports to convey knowledge.

One who makes an assertion incurs a risk through the aforementioned liability to error and, if Williamson is correct, is exposed to a conversational challenge. What if such a challenge is made? According to the view of Brandom (1983, 1994), in that case its issuer is obliged to respond with reasons that would justify the contested claim. Those reasons might invoke items of experience or the authority of others. The issuer of the assertion might even show that the speaker raising the challenge is committed to that proposition by her own convictions. If, however, the assertor is unable to convince the interlocutor of the assertion, others will become unable to defer to his or her authority if their own assertion of that same proposition is challenged.

In light of incurring a risk of error and exposing oneself to a conversational challenge, it might seem that asserting is more trouble than it is worth. Yet, asserting is the bread and butter of conversational life, so it presumably has redeeming points. First, one whose assertions turn out to be reliably correct, or at least widely accepted, garners credibility. That in turn is a source of social authority: We look to

reliable assertors to get things right. Second, it might be held that knowledge has intrinsic worth. Although making an assertion that is borne out is not a sufficient condition for knowledge (you might have gotten lucky or not have believed what you claimed), it is often associated with it. For this reason, getting things right by means of a correct assertion might be thought to be its own reward.

Third, an assertion that is not challenged, or is challenged but the assertor responds with an adequate defense of the claim, may be entered into conversational common ground. A conversation begins with a (possibly empty) set of propositions that interlocutors hold in common while being mutually aware that they hold this information in common. Among fans at a baseball game this common ground might include propositions about current weather conditions, the teams' score, and perhaps a few items in the current national news. Much more will typically be common ground among members of a tightly knit family, less among people waiting at a major bus terminal (Clark, 1996).

Let Σ_i be a commitment store for interlocutor i, containing all those propositions to which interlocutor i is committed. Where 1, . . ., n are interlocutors, we may define $\Sigma_{1\cap,\ldots,\cap n}$ as $\Sigma_1\cap,\ldots,\cap\Sigma_n$. Even if $P \in \Sigma_{i\cap j}$, it does not follow that P is in the common ground of i and j, for neither may have any commitments with regard to the other's commitment to P. Rather, where $s_1, \ldots, s_n$ are a group of interlocutors,

P is common ground among $s_1, \ldots, s_n$ (written $P \in \Sigma_{1\ldots n}$) iff
(a) for all $s_i \in \{s_1, \ldots, s_n\}$, $P \in \Sigma_i$, and for all $s_i \in \{s_1, \ldots, s_n\}$, $(a) \in \Sigma_i$.

$\Sigma_{1\ldots n}$ will in general be a proper subset of $\Sigma_{1\cap,\ldots,\cap n}$. When $s_1, \ldots, s_n$ are engaged in a conversation and s_i asserts that P, then so long as no other member of $s_1, \ldots, s_n$ demurs, $P \in \Sigma_{1\ldots n}$. This may bring about progress on a question at issue (Where is the bus station?; or Why is the child ill?) or may aid in the elaboration of a plan (of getting to the bus station or curing the child), and it enables speakers at a later time to presuppose P in their speech acts. For instance, once it is common ground that the child's illness is viral, we may presuppose this fact, as shown by the acceptability of a remark such as, "Since antibiotics will be useless on her, we need to ease her discomfort some other way." The use of the phrase, "Since antibiotics will be useless on her," would be inappropriate if it were not already common ground that the child's illness is viral and that antibiotics do not treat viral infections (see Green, 2000 for a fuller discussion).

In addition to enhancing inquiry and planning and to laying the foundation for later presuppositions, an assertion may generate other pragmatic effects. For instance, one who asserts P may also suggest, insinuate, or implicate a distinct proposition through the meaning of what one says: If one asserts that Mary was poor but honest, the use of "but" suggests that there is some tension between poverty and honesty. According to Grice's theory of implicature (1989), in that case one does not, however, assert that there is such a tension. Rather, what one asserts is true only in case Mary is poor and Mary is honest. Again, if someone asserts that Mary lost a contact lens, he or she will normally be taken to suggest that Mary lost one of her own contact lenses, rather than someone else's contact lens. This implicature, due not to the conventional meaning of any particular locution but rather to norms governing conversational practice, is also no part of what he or she asserts. When a speaker asserts P, he or she often means (specifically, speaker means) a good deal more without thereby asserting those other contents.

Assertions are not just beholden to the norm of accuracy about the world; they are also held to the norm of sincerity. One who asserts what one does not believe is a liar. By contrast, it is no lie conversationally to implicate what one does not believe. If in response to your question, "Where is Mary?" I reply that she is somewhere in Spain, I may implicate that I am in no position to be more specific. If in fact I do know that she is in Pamplona, I have been evasive, misleading, and perhaps even mendacious but no liar (Adler, 1997). Similarly an assertion of P, while representing oneself as believing that P, is not also an assertion that one believes that P. Were that so, one would literally contradict oneself in saying, "P but I don't believe that P." As G. E. Moore (1993) observed, however, although this utterance does seem absurd in some way, it is not a self-contradiction. What it says could well be true. Although an assertion of P is not an assertion that one believes that P, that assertion does express, manifest, or display one's belief that P. Current research is actively engaged with the relation between assertion and the states of mind that it manifests (Williams, 1996; Davis, 2003; Green and Williams, 2006).

Assessment of First Language Proficiency

D L Rubin and H-W Lim, The University of Georgia, Athens, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the earliest instances of high stakes first language (L1) assessment is reported in the biblical book of Judges, chapter 12. A civil war of sorts is being waged between two contingents of Israelites, the Gileadites and the Ephraimites. The Gileadites prevail, and seek to decimate the retreating troops who, not many years earlier, had been their compatriots. But how to discriminate foe from friend, since the Ephraimites are not marked by any obvious physical distinction? Indeed, both camps are comprised of speakers of the same language. Thus it is easy, when accosted, for members of the vanquished forces to simply deny their out-group membership. As it happens, however, a language proficiency criterion is advanced to discriminate losers from winners.

> And it was so, that when an Ephraimite who had escaped said, "Let me go over" that the men of Gilead said to him, "Are you an Ephraimite?" If he said, "No", they then said to him, "Say the word Shibboleth". If he said "Sibboleth", for he could not frame to pronounce it right, they took him and slew him at the passages of Jordan.

The Bible records that 42 000 individuals receive failing grades on that particular L1 proficiency exam.

Sociopolitical Issues in First Language Proficiency Testing

Language lies at the heart of national identity. It is key to attributing in-group status to individuals who share mutual values and loyalties (McGroarty, 2002). Standard varieties of languages evolve as ways of marking those to whom prestigious status will be accorded. To the degree that L1 proficiency is equated with facility at producing those standard varieties – as opposed to those who 'could not frame to pronounce it right' – L1 tests demand attention to far more considerations than mere psychometric adequacy. Rather, L1 testing is fraught with sociopolitical considerations (Ruth, 2003) about who is to be included among the anointed of a society, and who may be left to fear for their lives on the banks of the Jordan.

It might mistakenly appear tautological to remark that L1 testing is intended for native speakers. But as the prevalence and ambiguities of multilingualism become ever more evident, the very construct of 'native speaker' is called into question (A. Davies, 2001).

One of the earliest instances of high stakes first language (L1) assessment is reported in the biblical book of Judges, chapter 12. A civil war of sorts is being waged between two contingents of Israelites, the Gileadites and the Ephraimites. The Gileadites prevail, and seek to decimate the retreating troops who, not many years earlier, had been their compatriots. But how to discriminate foe from friend, since the Ephraimites are not marked by any obvious physical distinction? Indeed, both camps are comprised of speakers of the same language. Thus it is easy, when accosted, for members of the vanquished forces to simply deny their out-group membership. As it happens, however, a language proficiency criterion is advanced to discriminate losers from winners.

> And it was so, that when an Ephraimite who had escaped said, "Let me go over" that the men of Gilead said to him, "Are you an Ephraimite?" If he said, "No", they then said to him, "Say the word Shibboleth". If he said "Sibboleth", for he could not frame to pronounce it right, they took him and slew him at the passages of Jordan.

The Bible records that 42 000 individuals receive failing grades on that particular L1 proficiency exam.

Sociopolitical Issues in First Language Proficiency Testing

Language lies at the heart of national identity. It is key to attributing in-group status to individuals who share mutual values and loyalties (McGroarty, 2002). Standard varieties of languages evolve as ways of marking those to whom prestigious status will be accorded. To the degree that L1 proficiency is equated with facility at producing those standard varieties – as opposed to those who 'could not frame to pronounce it right' – L1 tests demand attention to far more considerations than mere psychometric adequacy. Rather, L1 testing is fraught with sociopolitical considerations (Ruth, 2003) about who is to be included among the anointed of a society, and who may be left to fear for their lives on the banks of the Jordan.

It might mistakenly appear tautological to remark that L1 testing is intended for native speakers. But as the prevalence and ambiguities of multilingualism become ever more evident, the very construct of 'native speaker' is called into question (A. Davies, 2001).

A sampling of national census questions over several years and countries reveals that the 'mother tongue' of which one is a native speaker might be officially defined variously as 'the language spoken by the individual from the cradle,' 'parent tongue,' 'thinking language,' 'language of their homes,' 'language of everyday use,' and so on (Pattanayak, 1998: 125). One may thus qualify as a native speaker of more than one language, achieve native proficiency in several languages, fail to achieve native-like proficiency in the language that is chronologically one's first while attaining native speaker status in a L2 or L3, or possess one native language for some communicative purposes and another native language for others. Perhaps the only indisputable fact about native language status is that everyone is a native speaker of at least some language some of the time (Muysken, 1998).

The inherent complexity of native speaker status is highly problematic for the L1 testing enterprise. First, it complicates the issue of exactly who should be eligible for L1 testing, and who will test instead as a speaker of an additional language. Recent studies show that third generation immigrants to the United States are overwhelmingly English dominant (Alba, 2004), yet many such students with Latino surnames are surprised to find themselves tested as English language learners and 'placed' into bilingual programs, often for years (Ravitch and Vitteriti, 1997; see also Nero, 1999 for the case of native speakers of Caribbean English assigned to ESL classes). Second, the lack of an unambiguous definition of L1 speaker status calls into question exactly what language variety test makers should adopt as criterial to language proficiency. Thus, for example, a governmental agency in Jamaica, West Indies, that requires prospective employees to demonstrate 'good English' might impose a standard that favors speakers of British English over those who speak the dominant native Jamaican acrolect (Irvine, 2004). Third, test makers cannot ignore the ethical consequences of measurement tools that inevitably perpetuate elitist class distinctions when proficiency is equated to approximation to a prestige language variety (Shohamy, 2001).

One strategy for overcoming these sociopolitical conundrums is to simply abolish artificial boundaries that distinguish tests of L1 proficiency from tests for speakers of additional languages. Proposals for simply arraying all speakers – native speakers along with speakers of additional languages – along a single continuum of assessment have some cogency, but do not really avoid the inevitable sociopolitical stratification between more native-like and less native-like that would nonetheless result (A. Davies, 2001).

Functional and Processural Criteria for Assessing L1 Speaking, Listening, Writing, and Reading

Another way to mitigate adverse sociopolitical effects of L1 testing is to adopt proficiency criteria focusing more on communicative, expressive, or information seeking *functions* of language (Programme for International Student Assessment, 2003; National Communication Association, 1998), or on literacy and oracy ***processes*** (Simons, 1971) rather than on degree of language accuracy as adjudicated by some standard or prestige variety. Emphasizing communicative and processural assessment criteria is consistent with views of language proficiency as **performed communicative competence**, rather than as decontextualized mastery of discrete formal features of language (e.g., National Council of Teachers of English and International Reading Association, 1994).

It is easiest to envision functional rather than formal criteria for L1 proficiency within the domains of speaking and listening. Thus, for example, students might engage in referential communication accuracy activities, in which quality points are assigned for the number of target pictures or items successfully encoded or decoded (Patterson, 1981), or raters might evaluate student presentations using rubrics that point to key rhetorical traits of specific oral genres, such as 'show and tell' (Michaels, 1986). Notwithstanding the relative ease of generating principled criteria for evaluating speaking and listening, oral language remains the least likely aspect of L1 to be the object of systematic evaluation. Several factors contribute to its neglect, including the costliness of real-time evaluation of speech performance, the difficulty in achieving inter-rater reliability, and the attitude that since oral L1 develops naturally, it need not receive much investment in the school curriculum (Pinnell and Jaggar, 2003; Rubin and Schramm, 1997). Often programs that are advertised as assessing oral language, especially among young children, are merely prereading inventories employing such criteria as memory of text and story sequencing (e.g., D. Davies, 2001). (Reviews of methods for assessing L1 oral can be found in Morreale and Backlund, 1996; Bostrom, 1997; Rubin and Schramm, 1997.)

With respect to L1 writing proficiency, the most widely known communicatively oriented mode of evaluation is primary trait rating (Lloyd-Jones, 1977), originally developed for use by the U.S. National Assessment of Educational Progress (NAEP; Persky *et al.*, 2002). Beyond its first decade, NAEP diluted the intended rhetorical specificity of

primary trait scales (Freedman, 1991), but the spirit of primary trait scoring – that is, to identify a small number of primary rhetorical demands of a particular writing prompt and to construct a scoring rubric that carefully delineates levels of fulfilling those demands – persists in many writing assessment scoring rubrics. (For a review of assessment procedures and types of scales, see Wolcott and Legg, 2001. For a review of mainly psychometric issues pertaining to L1 writing assessment – including the feasibility of computer scoring of writing samples – see Breland *et al.*, 1999.)

The problem with applying a primary trait scale to any writing sample – indeed, the problem with basing any high stakes decision on only a one-shot sample of language assessment performance – is that a single sample of written language collected under controlled testing circumstances and constrained by unnatural time limits cannot represent the full panoply of writing skills any literate individual possesses. Even the syntactic complexity exhibited in an individual's writing is hardly a stable stylistic trait. Rather, syntactic complexity in writing manifests low test-retest reliability (Fitzgerald and Shanahan, 2000). To enable assessment of a broad and representative sample of writing, a number of educators have advocated assembling and rating entire portfolios of writing (Freedman, 1991; Yancey, 1992). In a typical portfolio assessment, students themselves select work they wish to showcase from among several months of schoolwork. They might include multiple draft compositions and brief explanations about their evolution. Some of the work collected in the portfolio might have benefited from teacher input. Other work might very well have been the product of collaborative authorship. Often students write cover letters telling evaluators what they value in their portfolios. While the washback effect of this assessment technique to teaching language arts might be salubrious indeed, the utility of these kinds of unstandardized writing portfolios for discerning with any precision levels of competence in written language appears limited (Despain and Hilgers, 1992).

For the same reason that single-point tests of writing performance are seen as limited, some educators have likewise advocated use of portfolios for more broad-based assessments of reading (Tierney *et al.*, 1998). Indeed, earlier focus on comprehension as the main criterion for reading ability has made way for more holistic measures, including measures of metacognition and strategy, as well as reading attitudes and quality of literary experience (Farr and Beck, 2003). The measures developed by the 43-nation Programme for International Student Assessment (PISA; 2003) comprise a prime example of such a broad approach to L1 reading. PISA tasks for assessing the reading proficiency of 15-year-olds in school presume decoding and comprehension. Instead of evaluating these, they test abilities to (1) retrieve information, (2) interpret texts, and (3) reflect and evaluate. Thus, a high-difficulty item that tests information retrieval might ask test takers to use information in a footnote to locate information in a diagram. A mid-level interpretation item requires test takers to explain a character's motivation in light of sequenced events presented in a long narrative. A low-level reflection and evaluation item asks readers to justify a personal point of view based on evidence in a long narrative. Like many contemporary reading examinations (see, for example, Hill, 2004), the PISA items include both multiple choice and supplied-response formats. (For an overview of L1 reading assessment practices, see McKenna & Stahl, 2003.)

Beyond the Four Modalities of Language

The PISA test is noteworthy also because it includes among its reading passages, texts consisting not only of connected prose, but also of a variety of graphs, charts, and visual organizers. The PISA test blurs boundaries between traditional notions of reading and visual literacy. Indeed, an age of post-typographic 'new literacies' and hybrid modes of communication mediated by digital technologies demands an expanded notion of what it means to be proficient in one's L1 (Kinzer and Leander, 2003). As just one example, a December 2004 release of the U.S. government's *9/11 Commission Report* has been published by AV books on an MP3 CD. It contains video, audio, and searchable text. One may listen/view/read it on a number of electronic devices ranging from personal computers to Apple iPods. As writers learn to compose vertically as well as horizontally in hypertext, the illusion of linearity in text processing is forever put to rest (Bolter, 1998). As users select links to follow, or pass their pointing devices over one hot link or another, the distinction between reader and author passes into anachronism. As a new generation of students sits at their school desks surreptitiously 'chatting' via cell phone text messaging with students across the aisle – augmented by synchronous nonverbal gestures – speaking and writing merge into an as yet unnamed telegraphic yet expressive language modality. Despite the rapid diffusion of new literacies, at least among industrialized nations, methods for proficiency assessment in this domain have yet to be invented (Kinzer and Leander, 2003).

Integrated, Standard-Based Performance Assessment of L1 Proficiency

The hybrid quality of new literacies is an especially dramatic reminder that users rarely deploy just one language modality – listening, speaking, writing, reading – at a time, except perhaps in the artificial contexts of testing. Progressive L1 curricula move toward unifying language modalities in authentic inquiry-based learning (Peters and Wixson, 2003). At the same time, the movement for authentic assessment enjoins testers to assess student skills in meaningful contexts that permit a variety of performance modalities, rather than employing decontextualized test prompts that reveal only students' abilities to produce reductionistic responses on demand (Wiggins, 1989). Carefully articulated performance standards – including fully annotated exemplars of work products and behaviors at each level of quality – are necessary to implement meaningful, systematic assessment in the context of integrated language arts and authentic testing (Claggett, 1999).

L1 testers might look to the New Standards performance assessment project as a paradigm of just such an enterprise (Pearson *et al.*, 1998; Rubin and Hampton, 1998). Additional New Standards materials provide annotated work-products and even videotapes of oral language performances to be used for benchmarking rater judgments (e.g., New Standards, 1998, 2002). Publicly available benchmarked performance standards also render proficiency criteria transparent for test takers and for the teachers who prepare them. Moreover, New Standards performance objectives are integrated both within the language arts and across other learning domains. Integration within the language arts is represented, for example, by a task that asks a secondary school student to write a critique of a functional document, such as an assembly manual, for its use of graphics and layout conventions. Integration between language arts and other subjects is represented, for example, by a task that asks postsecondary students to give an oral presentation interpreting a series of line graphs that show interdependencies in shifting bird populations.

Implementation and Washback of L1 Proficiency Testing

It has become commonplace to remark that the validity and consequences of any testing process may vary depending on the users (students, teachers, education agencies, policy makers) and the uses (formative learner evaluation, individual classification, certification, selection decisions, program evaluation) of the resulting data. The landscape of L1 testing is littered with instances of psychometrically viable and even conceptually well-intended language proficiency assessments that ultimately limited or undermined the quality of instruction learners received (e.g., Hill, 2004; Ruth, 2003). When an assessment process, to the contrary, enhances instruction by reinforcing the teaching of proper proficiency criteria, it is said to have positive washback or consequential validity. It seems apparent that L1 assessments such as NAEP that emphasize writing performance and rhetorical criteria for proficiency have exerted positive washback on the teaching of writing (Moss, 1994). It is likewise anticipated that integrated L1 performance standard based assessment procedures such as New Standards may bring about substantial reform in L1 instruction (Pearson *et al.*, 1998).

Assessment of Second Language Proficiency

T McNamara, The University of Melbourne, Melbourne, Australia

Introduction

Language testing in the past decade has seen the rethinking of fundamental positions and attitudes. There have been important developments in the area of validity theory (how we understand the process by which tests yield meaningful information about test takers) as well as changes in our understanding of the socially constructed character of language test performance, new thinking about research methods (quantitative and qualitative) in language testing validation research, and an increasing realization of the political character of tests, including their role within social and educational policy. This article briefly discusses these developments and their implications for language testing research and practice in the context of current developments in validity theory.

Developments in Validity Theory

Language testing researchers (Bachman, 1990, 2005; Chapelle, 1998; Chapelle *et al.*, 2004; McNamara, 2000), drawing on work in educational measurement by (in particular) Messick, Mislevy, and Kane (e.g., Messick, 1989; Mislevy *et al.*, 2002, 2003; Kane, 1992, 2001), understand scores on language tests not simply as reports of performance in the test situation but as having meaning only as the basis for inferences beyond that situation. The real target of the assessment, the candidate's performance under nontest conditions, cannot be observed directly but is inferred from observations of test performance. Language tests resemble those experimental procedures in science that use hypotheses and reasoning from observable data to draw inferences about things that cannot be observed directly.

Given this, central to assessment is the chain of reasoning from the observations to the claims we wish to make about students. Mislevy *et al.* (2003) call this the 'assessment argument' (Figure 1); Kane uses the term 'validity argument' (Kane, 1992, 2001). Such an argument is needed to establish the relevance of assessment data to test score inferences – that is, the value of the test data as evidence. Articulation of the assessment argument is a requirement of any assessment system.

According to Mislevy *et al.* (2003),

> An assessment is a machine for reasoning about what students know, can do, or have accomplished, based on a handful of things they say, do, or make in particular settings. (p. 4)

The key element in this procedure is 'reasoning' – both about how adequately the target knowledge, skills, and performance abilities (the test domain or test criterion) are understood or represented theoretically in the test construct and about the relationship of the assessment procedures to the construct. (Obviously, the term 'machine' is used metaphorically, meaning a 'systematic procedure' or 'mechanism.')

Furthermore, the goal of assessment is to establish a basis for assertions about what students 'know, can do, or have accomplished.' Mislevy *et al.* (2003) refer to these assertions as 'claims.' This term is important because assessments often appear to yield definitive, authoritative, factual statements about test-takers; instead, we should recognize the assertions of tests as claims based on evidence and necessarily open to dispute.

Finally, the evidence for these claims, their basis in observations, is usually, for reasons of time and resource constraints, rather scant – 'a handful' of performances collected in the time available for an

Figure 1 The assessment argument.

assessment, often no more than 1 or 2 hours. These will include essays, diagrams, marks on answer sheets, oral presentations, utterances in a conversation, and so on. They are thus vulnerable because the evidence is necessarily incomplete.

Evidence-Centered Design

Assessment, then, is an act of interpretation; it yields only claims, never certainty. Any assessment system will need to embrace this fact and explicitly justify how the evidence provided by systematic observation of learner behavior forms an adequate basis for claims about the language capacities and language development of learners. Mislevy and colleagues (Mislevy *et al.*, 2002, 2003) recommend a principled procedure for relating the evidence available in test performance to the inferences we wish to make about the individual who has provided that evidence. This approach to building an assessment argument is known as Evidence-Centered design. The procedure involves a number of stages (Figure 2).

I focus only on the first two stages of this complex approach: domain analysis and domain modeling. The other stages will be discussed more briefly. An example will then be given of how this approach was used to inform a recent school-based language assessment development project.

Domain analysis is a preliminary research stage prior to the actual development of the test. It involves drawing on multiple sources of information to derive a definition of the test domain – what knowledge,

Figure 2 Evidence-centered design. Adapted from Mislevy *et al.* (2003, p. 6).

what performance tasks define it? For example, Tests of English for Academic Purposes, such as the International English Language Testing System (IELTS) or the new internet-based Test of English as a Foreign Language (TOEFL – iBT), are based in part on research identifying the communicative tasks facing international students studying in English-medium universities. In school settings, where assessment is related to the curriculum, the curriculum constitutes one such domain definition – a clear advantage of curriculum-related assessment because domain definition is already done.

The second and most important of the stages of Evidence-Centered design, domain modeling, has three substages: claims, evidence, and tasks. Together, the modeling of claims and evidence constitute the test construct.

In the first substage, the claims we wish to be able to make about students are formulated. These claims may lie along a continuum of specificity, from the general ('has advanced proficiency for his/her age/grade level') to the more specific ('a student can read to integrate information and arguments across multiple sources by generating an organizing frame that is not contained in any of those sources'). The choice of granularity of claims bears on the functions that the claims serve: certification for admission to work or study, the enhancement of curriculum-related learning, and so on. Frequently, a set of claims is presented as an ordered series, thus forming an assessment framework or statement of standards, the most important way in which assessment of language development is currently constructed. Examples include the standards that currently dominate thinking in U.S. school education, the Common European Framework of Reference for languages, and the descriptive bands of achievement in English for Academic Purposes that form the basis for reporting performance on tests such as IELTS.

The second substage of domain modeling is to consider the evidence – the things that we would like to observe a student doing – that will form the basis for claims. Engagement in what kinds of tasks would provide evidence to determine claims about the abilities of the person so engaged? Here, the results of the domain analysis will obviously be relevant. Also, what standard of performance is required? It is important to realize at this stage that the tasks here are not the tasks that appear in the test but, rather, the kinds of things we would like to be able to observe or capture in some way in the test; exactly how is the subject of the following substage. This second substage also involves articulating the aspects of the student's performance that we consider important: in other words, we need to determine the criteria by which it will be assessed. This is especially important for performance assessments, in which the student produces a whole spoken or written text, which is then judged subjectively against certain criteria. Ironically, or perversely, the test construct of an assessment scheme is often most clearly present, albeit implicitly, in the assessment criteria, yet centrality of criteria is neglected in many accounts of assessment theory.

The third and final substage involves determining how evidence will be collected – in other words, what tasks we will require students to engage in to enable us to observe them profitably. This raises the issue of the context and conditions of performance, which if not attended to properly can jeopardize the validity of the claims because of the introduction of construct irrelevant factors.

In the following stage of Evidence-Centered design, Mislevy *et al.* discuss the psychometric or measurement input into the process of test development. The discussion here is highly technical, and space precludes us from considering it further. In general, the hypothesized relationships of the domain modeling stage are now modeled statistically. This means that empirical evidence in the form of data from student test responses can be analyzed statistically to confirm the domain modeling. The data must also be analyzed to satisfy basic psychometric requirements of reliability (consistency of measurement), in both discrete-item and judge-mediated tests. Addressing these and other evidence-related issues involves increasingly sophisticated statistical methods; a helpful review of these developments is available in Bachman (2000). They include generalizability theory, item response modeling including Rasch modeling, and structural equation modeling. In addition, qualitative research methods (Lumley and Brown, 2005) are an increasing feature of language test validation, and include, in particular, the use of introspective methods in research on listening (including multimedia listening and viewing), the rating of writing, and many other topics. A survey of discourse-based studies of oral language assessment (McNamara *et al.*, 2002) identified a number of topics dealt with in such research and indicated the extensive range of qualitative research techniques used. In addition, significant studies of the validity of oral language tests have used a combination of quantitative and qualitative methods. For example, O'Loughlin (2001) combines Rasch analysis, lexical density counts of candidate discourse, and case studies of individual candidates to establish his claim about the lack of comparability of two supposedly equivalent instruments, direct and semidirect measure of oral proficiency. Iwashita *et al.* (2001) use a combination of Rasch analysis and

careful study of candidate discourse to reach important conclusions about the applicability of Skehan's model of task performance conditions to the definition of dimensions of task difficulty in a speaking test. Brown (2003) combines conversation analysis and Rasch analysis of scores to illuminate the character of interlocutor behavior in speaking tests and its impact on scores.

Emerging from these design processes is what we might call a technical blueprint for the assessment, including both for the design and administration of tasks and for collecting empirical data that can be used to check aspects of the validity of the modeling and other features of the assessment. (Confusingly, Mislevy calls the technical implementation blueprint a 'conceptual assessment framework,' but this term seems more suited to the earlier phase of domain modeling.) The final stage, then, is an actual operational assessment, which will include quality assurance mechanisms based on data from the assessment.

Developing a Language Assessment System: An Example

This section provides an illustration of how Mislevy's framework of claims, evidence, and tasks provides a useful context for the development of assessment systems in schools. A brief outline is given of how the framework was used in a project on the measurement of outcomes in the learning of Asian languages in Australian schools (Hill *et al*., 2004).

Given its geographical location, Australian government policy in recent years has promoted the study of Asian languages in Australian schools, to the point where Japanese and Indonesian for a number of years have rivaled traditional European languages such as French and German as the most popular languages learned in school; the demand for Chinese is increasing rapidly. In some areas of the country, the study of these languages is commenced at primary school level (covering the first 7 years of education, from kindergarten to year 6). As part of the evaluation of its policy promoting the study of Asian languages in schools, the Australian government wanted to establish whether the considerable expenditure in support of the policy had yielded measurable achievements in terms of learner proficiency. A complicating factor is that educational provision is the responsibility not of the federal government but of the eight states and territories of Australia, each of which has three distinct educational systems (government, Catholic, and independent non-Catholic). There was a need for coordination between these many different educational systems to agree on a single national set of measures to evaluate the outcomes of student learning. The project therefore aimed to develop nationally agreed key performance measures (KPMs) for two Asian languages, Indonesian and Japanese, at two transition points – the end of primary schooling (years 6/7) and the end of compulsory foreign language learning (year 10).

Given the diversity of provision (three different education systems in each of eight states and territories), each with its own curriculum and assessment frameworks, it was decided to use Mislevy's framework to organize the discussion of existing commonalities and possibilities for agreement across systems (Table 1).

Through an intensive series of consultations and workshops, administrators and teachers were engaged in discussions of how to formulate the claims, the kinds of evidence that would support these claims, and the way that evidence would be captured in task design. The KPMs represent the agreed claims that would be the target of assessment. The project went beyond claims, however, to evidence and broad task design, and in the discussions of these latter, opportunities for this evaluation project to serve the needs of teachers and learners were built in. It was agreed that there would be a mix of external standardized test measures for the skills of listening, reading, and writing, but that these would be supplemented by further writing and speaking tasks that would be more locally relevant and delivered by teachers but assessed externally using an agreed common set of scoring criteria. In addition, student training in self-assessment would be a feature of any data gathering because aggregated self-assessments have been shown

Table 1 Key performance measures for Asian languages project

Claims (+ reporting)	*Evidence*	*Tasks (design for data gathering)*	*Data collection*
What claims do we want to make about learners?	What evidence will we seek to support these claims?	How will we go about gathering this evidence?	*Writing, trialing, and administering assessment tasks*
In what terms will these claims be made?			
How will these be reported?			
[Scales]	[Student performances; task design]		

to be sufficiently reliable to constitute further evidence of system-level (not individual-level) achievement. In this way, in addition to this assessment serving external management purposes, it had the potential to be of lasting benefit to teachers and learners. It was found that those participating in the project related easily to this broad framework, and the project was completed successfully. The project did not require the development, trialing, and administration of actual tests (Table 1), but the blueprint for their development now exists.

I have discussed one approach to the development of an assessment argument, that of Mislevy, because it has not been widely discussed in the language testing literature despite the fact that it is playing an increasingly important role in the development of language assessments, such as TOEFL – iBT. An alternative and somewhat better known approach is that of Kane (Kane, 1992, 2001), who similarly proposes a number of logical steps in the development of any assessment scheme in order to tie test performance to valid inference about test-takers beyond the testing situation. He terms this process the development of an 'assessment argument.' Distinctively, he proposes that we consciously envisage threats to the validity of test score inferences and empirically investigate those as part of the test validation process. Kane's thinking is increasingly important in language testing: Useful introductions to it can be found in Chapelle *et al*. (2004) and Bachman (2005).

Messick on Test Validation: The Social Dimension

The work on validation by Mislevy, Kane, and others is heavily influenced by the thinking of Messick, who defines validity (Messick, 1989) as

> the degree to which empirical evidence and theoretical rationales support the adequacy and appropriateness of inferences and actions based on test scores or other modes of assessment. (p. 13)

Messick's thinking contains within it a concern for the social and political function of language tests that is addressed far less explicitly in the work of Mislevy and Kane – not at all, in the case of Mislevy, and imperfectly in the case of Kane. Bachman (2005) attempts to develop Kane's work in this regard by using Kane's approach to the development of a validity argument to consider the social consequences of test use, but the discussion only partly deals with the kinds of issues that have been raised to date in the discussion of the social and political functions of language tests.

Messick distinguishes a number of facets within his unified theory of validity (Table 2). The first cell in the matrix refers to 'empirical evidence and theoretical rationales' for the inferences we make in assessments. Mislevy and Kane can be read as elaborating and systematizing this requirement. The second cell on the top line stresses the need for test constructs to be relevant and useful in the context in which they are used: Not any test can be used for any purpose, no matter how sound the test may be. There is a tendency for people to believe (mistakenly) in the 'one best test' or to think that 'one test fits all.' For example, in the case of the assessment of the language and literacy development of children, 'off-the-shelf' tests may not be appropriate to the educational context, particularly if their relationship to the curriculum is unclear. The convenience of using such commercially available tests does not in itself form an adequate justification for their use. If a test developed in one context (e.g., IELTS, targeted at adult students intending to study at university or in training courses) is to be used in another (e.g., to assess the English language skills of non-native-speaking 15-year-olds in the transition from middle school in the home country to high school in an English-speaking country), then a new validation effort is required to support test score inference in the new context.

In the two lower cells in Table 2, Messick stresses, in a way that the work of Mislevy and Kane does not, the social and political values embodied in assessment constructs and the consequences of assessment practice.

The bottom left cell of Messick's matrix suggests that all test constructs, and hence all interpretations of test scores, involve questions of value. This means that educational assessment can never be 'objective' or 'scientific,' despite the fact that its daunting psychometric trappings and appeal to scientific rigor, and the authority that tests seem to possess, suggest otherwise. Messick sees all test constructs and practices

Table 2 Facets of validity

	Test interpretation	*Test use*
Evidential basis	Construct validity	Construct validity + relevance/utility
Consequential basis	Value implications	Social consequences

(From Messick (1989, p. 20).

as located in the arena of contestable values. This requires test developers to reveal and to defend the value implications of their test constructs. For example, in the case of literacy assessment, conflicting definitions of literacy involve differences in values, epistemologies, and ideologies, even where these are relatively 'naturalized,' as arguably in the case of the cognitive–psychological models of literacy that have been criticized by those taking a more social view. The adoption of a particular definition of literacy as the basis for a test will need to be defended in terms of the values and ideologies it implies. Recent work has drawn attention to the potential of poststructuralist thought in understanding how apparently neutral language proficiency constructs are inevitably socially constructed and thus embody values and ideologies (McNamara, 2001). It is worth noting that the deconstruction of such test constructs applies no less to constructs in other fields of applied linguistics, notably second language acquisition.

Similarly, traditional cognitively based constructs of individual proficiency that do not adequately theorize the contribution of interlocutors to the performance of individuals on speaking tasks may be questioned. This is obviously an issue in school-based assessments of young children, in which guidance from the teacher is fundamental in eliciting performance from the child, but it relates to a larger theoretical issue. During the past decade, there has been a growing critique of individualistic models of proficiency. A strong influence has been work on discourse analysis that stresses the coconstruction of performance (Jacoby and Ochs, 1995):

> One of the important implications for taking the position that everything is coconstructed through interaction is that it follows that there is a distributed responsibility among interlocutors for the creation of sequential coherence, identities, meaning, and events. This means that language, discourse, and their effects cannot be considered deterministically preordained . . . by assumed constructs of individual competence. (p. 177)

Research exploring the implications of this position for language testing has been most advanced in the area of oral language proficiency testing in face-to-face contexts, such as in the oral proficiency interview (Brown, 2003). This research demonstrates that the performance of the interlocutor is implicated in the performance of the candidate; this poses difficult questions for assessment schemes that are framed in terms of reports on individual competence.

Returning to Messick, in the final cell of the matrix (Table 2), he raises the issue of the impact of tests, particularly the wanted and unwanted consequences of test score interpretations (cell 4). The educational measurement field has responded strongly to the idea that exploration of the consequences of the use of language test scores be seen as part of test score validation. Although many theorists support this view (Kane, 2001), pointing out that validation of the use of test scores has been a central theme of the discussion of validity theory for more than 40 years, others (Popham, 1997) wish to restrict validation research to investigation of the accuracy of test score interpretation. In fact, Popham agrees that the consequences of test use are a subject requiring investigation, and he actively contributes to public discussions on what he views as the damaging consequences of school and college testing in the United States; he simply does not want to call it 'validation' research.

Within language testing, a concern to understand test consequences is increasingly evident. The educational impact of assessment schemes is the subject matter of studies of 'washback' (Cheng *et al.*, 2004). Of particular interest is the way in which teachers work with curriculum and assessment standards frameworks (Rea-Dickins, 2004).

A particularly difficult aspect of the impact of assessment schemes on educational outcomes has been a growing realization that many language test constructs are explicitly political in character and hence, when their influence is seen as negative, not amenable to influences that are not themselves political (Brindley, 2001). The most compelling examples include the way in which the Common European Framework of Reference for Languages (Council of Europe, 2001), a scheme that has been used to rationalize assessments across languages within Europe for the purposes of administrative and educational reform, has been widely criticized, among other things, for its view of language (Fulcher, 2004); however, critics face the realization that the mechanisms for modifying the constructs, or indeed of challenging the scheme in its entirety, are exclusively political. The political imposition of language testing constructs means that language test validation research will have an impact only to the extent that it is itself politicized; academic researchers have usually had limited success in such roles. A further example is the implementation of the No Child Left Behind Act of 2001 in the United States, which requires all states to introduce literacy assessments (among others) for grades 3–8. The impact of this policy on assessment, the way assessments are driving the curriculum, is being felt throughout school systems in the United States, but concern to resist the negative impacts of the assessments faces the hurdle of the political nature of the mandate requiring that such assessments be carried out, and carried out in particular ways.

Outside the educational sphere, the political character of language assessments is nowhere clearer than in the increasing use of language tests for control of refugee flows. The widespread use of language tests in processes to support the claims of asylum seekers to be from areas in which they have a justified fear of persecution is resulting in practices that have drawn increasing criticism regarding the validity of the sociolinguistic and sociophonetic constructs that underlie them and of the processes through which they are being implemented (Eades *et al*., 2003). Again, vigorous criticism from academic researchers has fallen on deaf ears politically. An attempt has been made to draw up guidelines for responsible professional practice in the conduct of such assessments, and they are being used in cases before the courts to evaluate the adequacy of assessments submitted as evidence.

These explicitly political considerations can also be understood in terms of test consequences. In the previous example of the asylum seekers, even if the procedure currently used was carried out on the basis of more adequate and defensible sociolinguistic constructs, and conducted more professionally, the entire procedure necessarily has serious consequences for those concerned and raises complex issues of the ethics of engagement in such work. The ethical responsibilities of language testers as an aspect of their professionalism is a major topic of debate within the field (Davies, 1997; Kunnan, 2000).

A more radical response to the issue of the consequences of test use involves direct political critique of the institutional character of assessment. Most significant is the work of Elana Shohamy (2001), who introduced the term 'critical language testing' to describe a research orientation committed to exposing undemocratic practices in assessment. This important work is still in its early stages. An example of the potential for critical archival research on language tests is the account in Spolsky (1995) of the political and institutional forces surrounding the initial development and struggle for control of TOEFL. Much more work is needed, for example, on critical responses to the use of language tests for immigration and citizenship within the context of inflamed intergroup relations in Europe and elsewhere. If language testers are to make an appropriate professional contribution to these debates, their training must prepare them not only to engage productively with the technicist orientation to validity of thinkers such as Mislevy and Kane but also to provide them with the conceptual skills necessary to make sense of the social and political context of their work so that they may act responsibly within it.

Definition

Assimilation is a phonological process in which two sounds that are different become more alike. (The opposite of assimilation is *dissimilation*, in which sounds that are alike become different.) Assimilation may be either *local*, in which the two sounds must be immediately adjacent, or *long distance*, where one sound affects another even though other segments intervene. Local assimilation is the most common type of phonological process, and it can occur along just about any phonetic dimension, including place, voicing, nasality, continuancy, rounding, and palatalization. Assimilations may be *partial* or *total*. In partial assimilation, one segment comes to match another in one or more, but not all, phonological features. In total assimilation, two segments become identical. Both partial and total assimilation can be illustrated with the English negative prefix in-. The basic form of the prefix is [in-], as in 'inaccurate' and 'insecure.' In 'impossible,' the [n] undergoes partial assimilation, changing to match the place of articulation of the following stop, but maintaining its underlying nasality. In 'illiterate,' the assimilation is total, with the [n] becoming identical to the adjacent [1].

Assimilations may also be distinguished by the direction in which the change occurs. In a sequence AB, if A changes to become more like B, as in [np] becomes [mp], the assimilation is termed 'regressive' (as though B were reaching back to change A) or 'anticipatory' (A anticipates a feature of B). If B changes to become more like A, the assimilation is termed 'progressive' (A reaches forward to affect B) or 'perseverative' (some feature of A perseveres into B). An example of progressive assimilation is found in the English past tense and plural suffixes, which are basically voiced (as in 'rowed' [ro-**d**] and 'toes' [to-**z**]), but become voiceless when preceded by a voiceless segment (as in 'cats' [kæ**t-s**] and 'talked' [ta**k-t**]).

Assimilation is sensitive to syllabic position and to prominence. For example, segments in the syllable coda assimilate to segments in the onset far more often than reverse (Itô, 1988; Beckman, 1998). Position in the word also plays a role: medial vowels assimilate to initial vowels, and affixes assimilate to roots. Steriade (2001) defines prominence in terms of perceptual salience, arguing that segments assimilate

Definition

Assimilation is a phonological process in which two sounds that are different become more alike. (The opposite of assimilation is *dissimilation*, in which sounds that are alike become different.) Assimilation may be either *local*, in which the two sounds must be immediately adjacent, or *long distance*, where one sound affects another even though other segments intervene. Local assimilation is the most common type of phonological process, and it can occur along just about any phonetic dimension, including place, voicing, nasality, continuancy, rounding, and palatalization. Assimilations may be *partial* or *total*. In partial assimilation, one segment comes to match another in one or more, but not all, phonological features. In total assimilation, two segments become identical. Both partial and total assimilation can be illustrated with the English negative prefix in-. The basic form of the prefix is [in-], as in 'inaccurate' and 'insecure.' In 'impossible,' the [n] undergoes partial assimilation, changing to match the place of articulation of the following stop, but maintaining its underlying nasality. In 'illiterate,' the assimilation is total, with the [n] becoming identical to the adjacent [1].

Assimilations may also be distinguished by the direction in which the change occurs. In a sequence AB, if A changes to become more like B, as in [np] becomes [mp], the assimilation is termed 'regressive' (as though B were reaching back to change A) or 'anticipatory' (A anticipates a feature of B). If B changes to become more like A, the assimilation is termed 'progressive' (A reaches forward to affect B) or 'perseverative' (some feature of A perseveres into B). An example of progressive assimilation is found in the English past tense and plural suffixes, which are basically voiced (as in 'rowed' [ro-**d**] and 'toes' [to-**z**]), but become voiceless when preceded by a voiceless segment (as in 'cats' [kæ**t-s**] and 'talked' [ta**k-t**]).

Assimilation is sensitive to syllabic position and to prominence. For example, segments in the syllable coda assimilate to segments in the onset far more often than reverse (Itô, 1988; Beckman, 1998). Position in the word also plays a role: medial vowels assimilate to initial vowels, and affixes assimilate to roots. Steriade (2001) defines prominence in terms of perceptual salience, arguing that segments assimilate

in contexts where contrastive features can not be clearly heard: postvocalic consonants generally assimilate to prevocalic consonants, because release into a vowel provides the most salient cues to the phonological features of a consonant.

Examples

Local Assimilation, Partial

One of the most common assimilations crosslinguistically is nasal consonants assimilating in place of articulation to a following stop. Examples include English 'inaccurate' vs. 'impossible' and 'compact' vs. 'contact' vs. 'co[ŋ]gress.' In Twi, the negative prefix is also a nasal: [me-m-pɛ] 'I do not like,' [me-n-tɔ] 'I do not buy,' [me-ɳ-ɳa] 'I do not receive,' [me-ŋ-ka] 'I do not say.' For Catalan (Catalan-Valencian-Balear), Kiparsky (1985) reported nasal assimilation to seven different places of articulation:

(1)	so[n] amics	they are friends
	so[m] pocs	they are few
	so[ɱ] felicos	they are happy
	so[n̪] [d̪]os	they are two
	so[ɳ] rics	they are rich
	so[ɲ] [y]iures	they are free
	so[ŋ] grans	they are big

The feature [nasal] itself may assimilate (Cohn, 1990; Piggott, 1992; Walker, 1998). Vowels often become nasal adjacent to a nasal consonant. In French, [bon] 'good' becomes [bõ]. In Sundanese (Sunda), [**ŋa**tur] 'arrange' is pronounced [**ŋã**tur] (Robins, 1957). Assimilation of nasality from consonant to consonant is found in Twi, when a root-initial voiced stop follows the negative prefix: [me-**g**u/] 'I pour,' [me-**ŋ-ŋ**u] 'I do not pour.'

Another common assimilation is voicing assimilation. Clusters of obstruents often assimilate in voicing, usually regressively. In Russian, for example, a string of obstruents always agrees in voicing with the final obstruent in the sequence: [o**d vz**bútʃki] 'from a scolding,' [o**t fsp**léska] 'from a splash' (Jakobson, 1978). Generally, sonorants do not participate in voicing assimilation (note that the [l] in [fspléska] neither becomes voiceless nor causes the preceding consonants to become voiced), though there are cases of sonorant–obstruent voicing assimilations. Postnasal voicing is attested in a number of languages, for example Kikuyu (Gikuyu) [**t**ɛm-a] 'cut-IMP,' [**n-d**ɛm-ɛɛtɛ] '1SG-cut-IMPERF' (Clements, 1985; see also Hayes, 1999 and Pater, 1999 for further examples and discussion). Voicing assimilation from consonant to vowel is found in Japanese, where high vowels become voiceless if surrounded by voiceless consonants: [ko**k̟u̥s**ai] 'international,' [**ki̥t**ai] 'expectation' (Tsuchida, 1996).

In Ancient Greek, obstruent clusters assimilated in both voicing and aspiration (Smyth, 1920): [gra**p**^{h}-o] 'I write,' but [gɛgra**p-t**ai] 'has been written' and [gra**b-d**en] 'writing/scraping'; [tri**b**-o] 'I rub,' but [tetri**p-t**ai] 'has been rubbed' and [etri**p**^{h}-**t**^{h}e:n] 'it was rubbed.'

Vowels and consonants sometimes influence one another. In many languages, coronal consonants become alveopalatals before high front vowels or glides, assimilating the higher tongue position. English has alternations such as grade/gradual ([d]/[dʒ]), habit/habitual ([t]/[tʃ]), press/pressure ([s]/[ʃ]). A vowel may also impose palatalization as a secondary articulation on a consonant, adding an additional high front tongue position without changing the consonant's primary place: Russian [ʒe**n**-a] 'wife,' [ʒe**n**^{j}-**i**-t^j] 'marry.'

The change of a stop to a fricative between vowels, as in Spanish [**b**ola] 'ball,' [l**a β**ola] 'the ball,' is sometimes considered assimilation of the feature [+continuant]. Assimilation of [-continuant] may be seen in postnasal hardening: Kikuyu [**β**ur-a] 'lop off-IMP,' [**m-b**ur-eete] '1SG-lop off-IMPERF' (Clements, 1985).

Local Assimilation, Complete

Several African languages have rules of complete vowel assimilation at word boundaries (Welmers, 1973). In Yoruba, for example, [ow**o**] 'money' plus [**e**po] 'oil' becomes [ow**ee**po] 'oil money.' In Igbo, [nwok**e**] 'man' plus [**a**] 'DET' becomes [nwok**aa**] 'that man.'

Total assimilation of consonants is found in English [in-] assimilation to [l] and [r] (mentioned above) as in 'illegal' and 'irreconcilable.' Another example of complete assimilation involving [l] is found in Arabic: the [l] of the definite prefix [ʔal] assimilates completely to a following coronal consonant: [ʔal-kitaab] 'the book' but [ʔaʃ-ʃams] 'the sun,' [ʔad-daar] 'the house,' [ʔan-nahr] 'the river' (Kenstowicz, 1994).

Long-Distance Assimilation

Long-distance assimilation is known as *harmony*. Vowel harmony is a type of assimilation in which all vowels in a certain domain (usually the word) must agree in one or more features. Vowel harmony has been extensively discussed in the phonological literature, and harmony systems involving backness, rounding, vowel height, and advanced vs. retracted tongue root have been described: see van der Hulst and van de Weijer (1995) for an overview. In

Hungarian, for example, suffix vowels assimilate in backness to the root vowel: [ha:z-nak] 'to the house,' [va:ros-nak] 'to the city,' [vi:z-nek] 'to the water,' [yr-nek] 'to the gap' (Ringen, 1988; see also Vago, 1976, Goldsmith, 1985). In Turkish, high vowels agree with a preceding vowel in both backness and rounding, while nonhigh vowels agree in backness. Some oft-cited examples from Turkish (Clements and Sezer, 1982) include:

(2) genitive sg.	genitive pl.	
ip-in	ip-ler-in	'rope'
kɨz-ɨn	kɨz-lar-ɨn	'girl'
jyz-yn	jyz-ler-in	'face'
pul-un	pul-lar-ɨn	'stamp'

In many West African languages, all vowels in a word must agree in the feature [advanced (or retracted) tongue root] (Welmers, 1973; Archangeli and Pulleyblank, 1989, Zsiga, 1997). In Igbo, [ɔ-sɪ-ala] 's/he has told' contains only vowels from the retracted set, [o-si-ele] 's/he has cooked' has vowels only from the advanced set.

Several Austronesian languages exhibit long-distance nasal harmony. Nasal assimilation in Sundanese (Robins, 1957; Cohn, 1990) may extend over a sequence of vowels and glides: [ɲãĩãn] 'wet.' Rose and Walker (2004) discuss nasal harmony from consonant to consonant in Kikongo (Kango): [m-bud-**idi**] 'I hit,' [tu-ku**n-ini**] 'we planted.'

Consonant harmony such as that seen in Kikongo is less common than vowel harmony. Attested cases involve long-distance assimilation of nasality, laryngeal features, and subsidiary place features such as [retroflex] or [anterior] (Hansson, 2001; Rose and Walker, 2004). One well-known example is anterior assimilation in Chumash (Poser, 1982): all coronal fricatives and affricates in a word must agree with the rightmost fricative or affricate in the value of [+/-anterior]: [k-sunon-us] 'I obey him,' [k-ʃunon-ʃ] 'I am obedient.'

Finally, tone may assimilate from vowel to vowel, or syllable to syllable. In Shona, for example, a string of suffixes following a low toned root will be low toned ([èrèŋg] 'read,' [kú-èrèŋg-ès-èr-à] 'to make read to') and a string of suffixes following a high-toned root will be high toned ([téŋg] 'buy,' [kú-téŋg-és-ér-á] 'to sell to') (Myers, 1990; Kenstowicz, 1994). The long-distance behavior of tone was instrumental in the development of the theory of 'autosegmental' 'phonology' (Goldsmith, 1976, discussed below).

Some Assimilations That Do Not Occur

The feature [+/-consonantal] does not assimilate. Vowels adjacent to consonants do not become consonants, and vice versa (though a possible counterexample is proposed by Kaisse, 1992). Nor does the feature [sonorant] assimilate, except as a byproduct of nasal assimilation or complete assimilation. The sequence [dr], for example, does not become [lr]. Stress does not assimilate. An unstressed syllable adjacent to a stressed syllable does not become stressed – rather the opposite: two adjacent stressed syllables or two adjacent unstressed syllables are avoided.

Assimilation and Phonological Theory

If linguistic theory is concerned with the question of 'What is a possible human language?' then phonological theory must be concerned with the question of 'What is a possible process of assimilation?' The best theory would be powerful enough to encode all actually occurring assimilatory patterns, but constrained enough to rule out impossible patterns.

Feature-Changing Rules

In the formal theory of Chomsky and Halle (1968), processes of assimilation were expressed as feature changing rules of the form A → B/ C__D ('A' changes to 'B' in the context of CAD). The crucial concept of feature 'matching' in assimilation was expressed via 'alpha notation.' Greek letters stand for variables over '+' and '−,' and every instance of the variable in a rule must be filled in with the same value. Thus

(3) [-sonorant] → [αvoice]/ ____ [-sonorant, αvoice]

would be read 'an obstruent agrees in voicing with a following obstruent.'

The Catalan nasal assimilation rule in (1) above would be:

(4) [+nasal] →	[α coronal]/	____	[α coronal]
	[β anterior]		[β anterior]
	[γ labial]		[γ labial]
	[δ back]		[δ back]
	[ε high]		[ε high]
	[ϕ distributed]		[ϕ distributed]

Feature-changing rules, however, are both too powerful, and not powerful enough (Bach, 1968; Anderson, 1985). They are too powerful in that nothing rules out impossible rules like that in (5):

(5) [-sonorant] → [αvoice] / ____ [-sonorant, αback]

In this rule, a consonant's voicing value must match its feature for back, yet this impossible rule is identical in formal complexity to the common rule of obstruent voicing assimilation. Feature-changing rules are not powerful enough, however, in that the

common and straightforward process of nasal place assimilation is represented via a complicated formula.

Feature-Spreading Rules

In the theory of 'autosegmental phonology,' assimilation is formalized as 'feature spreading.' A feature is linked to a segment via an association line, and features may spread (assimilate) via the addition of further associations. Obstruent voicing assimilation would be formalized as in (6).

(6)

The voicing feature begins as a property of the second consonant in the cluster (indicated by the solid line), but comes to be shared between the two (indicated by the addition of the dotted line). Thus assimilation is given a privileged status as an elementary operation, while more complicated feature switches have a correspondingly more complicated representation. Long-distance assimilation is easily handled as spreading over longer domains. The features [sonorant] and [consonantal] form the 'core' of the segment, the 'root node,' and do not themselves spread.

Different hierarchical groupings of autosegmental features ('feature geometries') have been proposed to account for the fact that certain groups of features (such as the place features in Catalan or the laryngeal features in Greek) assimilate together (Clements, 1985). If all of the place features are grouped under a single node, then place assimilation can be formalized as the addition of a single association line, the formal simplicity mirroring the rule's ubiquity.

(7)

Consensus has not been reached, however, on a universal geometry that can capture all the relevant groupings needed. Harmony systems such as Turkish, where [back] and [round] (but not other vowel features) spread together, have proven problematic. Another challenge is accounting for the fact that consonants are sometimes transparent to vowel assimilations (as in vowel harmony), and sometimes participate in vowel assimilations (as in palatalization). McCarthy (1988), gave an overview of one widely accepted geometry. Hume (1992) and Clements (1993) suggested a different set of class nodes, and Padgett (1995) provided an alternative, nonrepresentational account of feature classes in assimilation.

Constraints

In a nonderivational constraint-based theory such as 'optimality theory' (Prince and Smolensky, 2004), there is no reference to rules or processes of assimilation. Rather, 'markedness constraints,' which define preferred and dispreferred linguistic structures, are argued to prefer sequences where features agree, or where features spread over a certain domain. Such constraints may be grounded in either ease of articulation (e.g., switching voicing in the middle of an obstruent cluster is hard) or ease of perception (e.g., cues to place of articulation in preconsonantal nasals are hard to hear.) Specific assimilations are seen in languages that give specific markedness constraints high priority, and are not seen in languages that give higher priority to maintaining underlying specifications. Kaun (1995), Beckman (1998), and Bakovic (2000) provide constraint-based accounts of vowel harmony. Lombardi (1999) discusses voicing assimilation, and Padgett (1995) provides an account of nasal place assimilation. McCarthy (2004) provides a critical review of ALIGN and SPREAD constraints, and proposes an alternative analysis.

Assimilation vs. Co-articulation

Phonological assimilation can be distinguished from phonetic 'co-articulation.' Daniel Jones, in his 'Outline of English phonetics' (1940), distinguished 'assimilation,' which he defined as a change in phonemic status, and 'similitude,' in which two sounds become more alike but do not change their phonemic identity. In the foregoing discussion, it has been assumed that phonological assimilation results in a change in a segment's phonological features (from [+voice] to [-voice], for example), and thus the segment's phonological category. In co-articulation, there is no change in phonological category, but only in phonetic realization. Two articulatory gestures overlap in time, and thus may exert a physical influence on one another. For example, the [k] in 'key' is pronounced further forward than the [k] in 'coo,' because the former is overlapped in time (coarticulated) with a front vowel and the latter is coarticulated with a back vowel. In English, vowels are nasalized before a nasal consonant, because the velum begins to open before closure for the consonant is achieved (Cohn, 1990). Phonological assimilation is complete and categorical; phonetic coarticulation may be gradient and variable (Keating, 1990).

It may sometimes be difficult, however, to empirically distinguish the two. Browman and Goldstein (1990, 1992), in the theory of 'articulatory phonology,' showed that overlap and blending of articulatory gestures can result in apparently complete assimilation without any change of phonological features. They argue that in phrases like 'hundre[b] pounds' and 'i[m] pairs' the word-final coronal is still articulatorily present, as shown by phonetic imaging techniques. Assimilation is perceived because a coronal and a labial pronounced at the same time sound like an assimilated labial. Assimilation of alveolar [n] to dental [θ], as in the pronunciation of 'ten things' in English, or in the Catalan case discussed above, can also be accounted for in terms of articulatory overlap, as two different overlapping gestures blend to an intermediate place of articulation.

Articulatory phonology argues that all assimilations can be accounted for in terms of gestural overlap. Studies such as Cohn (1990) and Zsiga (1995, 1997), however, showed that categorical and gradient processes of assimilation must be distinguished. Cohn (1990) described both gradient and categorical processes of nasal assimilation. Zsiga (1995) showed that the categorical assimilation of [s] to [ʃ] in 'pressure' is qualitatively and quantitatively different from the partial and gradient change in the phrase 'press your point.' Zsiga (1997) examined Igbo [ATR] vowel harmony and vowel assimilation, showing that harmony is categorical and featural, while assimilation (except in some very common phrases like [nwoka-a] from [nwoke-a]) is gradient and the result of gestural overlap. It is argued that phonological features may be mapped into articulatory gestures, but that the phonological and phonetic modules should remain separate.

Is All Assimilation Local Assimilation?

Articulatory phonology has been extended to account for vowel harmony and other long-distance assimilations. Gafos (1999) proposed that harmonizing features should be understood as a single underlying gesture that persists throughout a word. Consonants do not break up sequences of harmonizing vowels, for example, but are overlaid on contiguous vowel gestures. From this point of view, all assimilation is local assimilation. 'Transparent' segments (vowels and consonants that intervene in a harmony domain but that apparently do not share the harmonizing feature) are obviously a problem for this approach. NíChiosáin and Padgett (2001) and Rose and Walker (2004) suggested various means by which such apparent 'action-at-a-distance' can be reanalyzed, and all assimilation be constrained to be strictly local.

Conclusion

Assimilation is the most common of all phonological processes, and thus has played an important role in phonological theory. Phonological theories have sought to capture what sorts of assimilation can and cannot occur, what groups of features assimilate together, and why certain segments participate in assimilations while others do not. Current work on assimilation is teasing apart the contributions of articulatory coarticulation and phonological feature switch, and continues to examine the proper formalization of local and long-distance assimilations.

Association for Computational Linguistics

G Hirst, University of Toronto, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

The Association for Computational Linguistics (ACL) is the primary international organization promoting research in computational linguistics and related topics. It organizes several series of conferences, publishes the journal *Computational Linguistics*, and maintains a large online archive of research papers.

The ACL was founded in 1962 as the Association for Machine Translation and Computational Linguistics, with Victor H. Yngve as its first president. However, the words *machine translation* were deleted from the name a few years later because of the cloud that hung over that enterprise at the time (*see* **Machine Translation: History**). Much of the growth of the association in subsequent years was attributed to the work of Donald E. Walker, who was president in 1968 and secretary-treasurer (in effect, administrator) from 1976 until his death in 1993.

In 1974, the association started publishing *The American Journal of Computational Linguistics,* edited by David G. Hays. This journal was notable in part because it was published on microfiche. Each issue consisted of a set of microfiche – one per article – plus a printed index card for each article that provided its title, author, and abstract. At the time, it was believed that this form of publication was the way of the future and soon every researcher would have a microfiche reader on his or her desk. This soon proved to be incorrect; a printed form of the journal was added in 1980, and the microfiche version was phased out a few years later. The title of the journal was changed to *Computational Linguistics* in 1984 to reflect its increasingly international orientation.

The ACL organizes an annual international conference on computational linguistics, and additional conferences are organized in most years by its North American and European chapters. Unlike most manuscripts written for academic conferences, papers submitted for presentation are fully refereed in the style of journal papers, and only a minority are accepted; consequently, ACL conference proceedings are regarded as archival research publications whose status is equal to that of a journal. In addition, the ACL and its 11 special-interest groups organize many annual workshops, usually in conjunction with the conferences.

In 2002, the association began the development of a complete, freely accessible Web archive of all its publications in computational linguistics. The archive includes almost all papers published in the association's journal or presented at its conferences and workshops since its inception, as well as additional papers from some other related conferences.

Associationism and Connectionism

J N Williams, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

Associationism maintains that all knowledge is represented in terms of associations between ideas, that complex ideas are built up from combinations of more primitive ideas, which, in accordance with empiricist philosophy, are ultimately derived from the senses. Connectionism is a more powerful associationist theory than its predecessors (Shanks, 1995) that seeks to model cognitive processes in a way that broadly reflects the computational style of the brain. The brain carries out millions of computations simultaneously in densely interconnected networks of

neurons. Information is represented as distributed patterns of activity, and learning is achieved by modifying the strength of connections between neurons. Connectionist or 'parallel distributed processing' models attempt to capture these general properties in highly artificial neural networks. These are self-organizing systems that discover for themselves the representations required to perform a specific task stipulated by the researcher. Their main interest lies in the fact that they display emergent rule-like behavior. The question is whether their learning trajectory, ultimate performance, and breakdown after damage mimic that of humans. Connectionist research provides an empirical means of evaluating whether associationist learning principles are sufficient to explain specific aspects of human behavior.

The simplest kind of connectionist network consists of a single layer of neuronlike units, in which each unit represents a predefined feature that can be activated by external input. Each unit is connected to every other unit by a connection whose strength, or 'weight,' determines the amount of 'activation' that passes along it. During training, when two units are simultaneously active, the strength of the connection between them is increased. Through this associationist learning principle, the network absorbs the correlational structure of the input and comes to represent concepts as distributed patterns of activity over its processing units. It has been demonstrated that representations of multiple individual instances of experience can be encoded in a single network and retrieved from partial cues by a process of pattern completion, while less specific cues prompt the retrieval of a prototype (McClelland and Rumelhart, 1985). Concepts can be thought of as 'attractor basins' in a multidimensional space of possible network states, an idea that has proved useful in explaining semantic errors in dyslexia (Hinton and Shallice, 1991) and in modeling semantic priming (Masson, 1995).

More complex networks are required when the problem involves mapping between different kinds of representation, for example, converting from orthography to phonology in single-word reading. Separate layers of units encode input and output representations, and typically, there is an intermediate layer of 'hidden' units whose function is to represent the input in a form that can be mapped onto the output (it is these hidden units that increase the computational power of connectionist networks compared to earlier associationist theories). During training, for each input pattern, the degree of error on the output is used to modify connection weights within the network so as to reduce the error in future. Using this 'back-propagation' learning algorithm, the network's behavior is gradually shaped until, ideally, it produces the correct output for the entire set of training examples. Of course, connectionist models would not be very interesting if all they did was store the input–output mappings they were trained on. What is critical is whether, after training, they exhibit humanlike performance. Models of word reading have been particularly successful in this respect. They produce humanlike responses to nonwords, showing generalization to items that they were not trained on, and they mimic subtle aspects of reading known words, such as the combined effects of regularity and frequency (Plaut *et al.*, 1996; Seidenberg and McClelland, 1989). This suggests that they extract knowledge of underlying regularities, rather than merely storing the specific items received during training. It is also claimed that, when damaged (e.g., by removing some of the connections), they show similar patterns of behavior to brain-damaged patients, and that different dyslexic syndromes can be simulated by damaging the network in different regions (Plaut *et al.*, 1996).

Another area of intensive connectionist research has been in relation to the English past tense. In this case, phonological representations of word stems are mapped onto phonological representations of past tense forms. It has been claimed that these networks mimic the human developmental profiles for regular and irregular forms, and for subgroups of irregulars (Plunkett and Marchman, 1993; Rumelhart and McClelland, 1986). They are also able to produce humanlike past tenses for nonce forms (MacWhinney and Leinbach, 1991), despite containing no discernible rule-like representations. By damaging a network in different regions, it is possible to simulate the kinds of dissociations between regular and irregular morphology found in brain-damaged patients (Joanisse and Seidenberg, 1999), paralleling the effects obtained in word reading.

Language processing also has an obvious sequential component. To deal with this, 'simple recurrent networks' are taught to predict each successive item in a sequence, using a record of the hidden unit activations to previous events. Not only do such networks learn to reproduce sequences, but they also extract the transition probabilities between items across the entire training set. There are simple recurrent network models of single word production that make humanlike speech errors (Dell *et al.*, 1993), and models of speech recognition that use phoneme transition probabilities to help locate word boundaries in continuous speech (Christiansen *et al.*, 1998; Elman, 1990). Models of syntactic processing use transition probabilities between words to form internal representations that reflect word classes (Elman, 1990). Such networks can also make structure-dependent

predictions over long distances and show sensitivity to embedding and recursion, suggesting that they could form the basis of a connectionist approach to syntactic processing (Elman, 1993).

Connectionism challenges a number of assumptions of traditional, 'classical' approaches to studying language and the mind. The classical approach sees rule knowledge as being represented in symbolic form, while exceptions to rules are stored in memory (Pinker, 1994; Ullman, 2001). Connectionist models produce rule-like behavior, yet they contain no symbolic representations. Rule-like behavior emerges as a consequence of the way in which individual instances of experience are stored in a single memory system. The connectionist challenge has provoked sustained debate (beginning with Fodor and Pylyshyn, 1988), focusing recently on the necessity for symbolic, or algebraic, rules (cf. Marcus *et al.*, 1999; Seidenberg and Elman, 1999) and the separation between rule knowledge and item memory, particularly in relation to the English past tense (Pinker and Ullman, 2002 and commentary). The reason for this heated debate is that connectionism challenges the classical assumptions about modularity, domain specificity, and innateness (as expressed in Pinker, 1994). The same neural architectures and learning algorithms are applied to linguistic and nonlinguistic domains alike, and no information is encoded in connectionist networks that is not ultimately derived from the input. Issues such as the poverty of the stimulus, universals, critical periods, and robustness have to be approached from novel perspectives (Elman *et al.*, 1996).

Connectionism has inspired new ways of thinking about language processing and learning. It emphasizes the statistical properties of the input and how complex behaviors are the outcome of multiple, competing constraints. This has motivated empirical work looking at human abilities to learn by tracking statistics (Saffran, 2001) and has provided the theoretical foundation for interactionist and 'constraint satisfaction' approaches to sentence processing and learning (MacDonald *et al.*, 1994; MacWhinney, 1987). Whether or nor connectionism in its purest form will be able to explain all aspects of language processing and learning is an empirical question. But connectionism has stimulated debate and focused empirical research on fundamental issues in the language sciences.

For a general introduction to connectionism, including reprints of seminal articles, see Ellis and Humphreys (1999). For reviews of language-related work, see the special issue of *Cognitive Science* (1999, *23(4)*) and Plaut (2003).

Audio-visual Speech Processing

R Campbell, University College, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The mouth, lips, tongue, teeth, and jaw systematically shape the pattern of sound that a talker produces. That is, the production of speech sounds has visible consequences. What bearing does this have on our understanding of speech and language mechanisms, and what are people doing when they read speech from facial actions?

Most of us, much of the time, do not need to see the talker to understand what has been said. For this reason, as much as any other, the acoustic properties of speech have constituted the major focus of research in speech science. Interest in audiovisual speech is rekindled from time to time by several factors: One is the need to communicate in noisy environments. Engineers try to find ways of increasing message redundancy by providing both visible and audible speech information. It has been estimated that seeing the talker offers a gain equivalent to around a 15 dB increase in signal-to-noise ratio for users of English. A second reason for interest in audiovisual speech is the rapid development of computer models of human action: Rewards are high for developing naturalistic, computer-generated visible speech, driven by a real actor's voice or from text (*see* http://mambo.ucsc.edu; Stork and Henneke, 1996; Massaro, 1998; Massaro *et al.*, in press). From the speech-perception point of view, non-acoustic aspects of the speech signal need to be considered in order to develop adequate models of natural speech comprehension. The variability in the signal that arrives at the listener's ears is a problem for a purely acoustic perceptual system. Does adding the talker's face and body improve the reliability of such analysis, and if so, how? In another realm, that of hearing loss and hearing remediation, and especially cochlear implant development, seeing the speaker's speech is a critical determinant of the ease and utility of hearing-aid use (see Bergeson and Pisoni, 2004, for review of this field).

A key finding, which reinvigorated the study of audiovisual speech processing, was that of McGurk and MacDonald (1976), who demonstrated that a heard syllable, presented in a quiet setting, could be influenced by a face that appeared to be saying something else. They showed that seeing 'ga' while hearing 'ba' led to the impression that 'da' had been spoken. This effect was not a unique demonstration of the influence of vision on audition, but it was the first time that the phenomenal report of a heard speech sound was categorically different depending on whether the eyes of the perceiver were opened or closed. The effect is powerful, robust, and relatively automatic. It can be demonstrated in children. The underlying mechanism is not difficult to unpick in general terms: 'ba,' 'ga,' and 'da' are acoustically similar, differing in terms of spectral features that are easily lost in noise. By contrast, the visible distinction between 'ba' (lips closed for the initial consonantal plosive) and 'ga/da' (mouth open) is reliable and

The mouth, lips, tongue, teeth, and jaw systematically shape the pattern of sound that a talker produces. That is, the production of speech sounds has visible consequences. What bearing does this have on our understanding of speech and language mechanisms, and what are people doing when they read speech from facial actions?

Most of us, much of the time, do not need to see the talker to understand what has been said. For this reason, as much as any other, the acoustic properties of speech have constituted the major focus of research in speech science. Interest in audiovisual speech is rekindled from time to time by several factors: One is the need to communicate in noisy environments. Engineers try to find ways of increasing message redundancy by providing both visible and audible speech information. It has been estimated that seeing the talker offers a gain equivalent to around a 15 dB increase in signal-to-noise ratio for users of English. A second reason for interest in audiovisual speech is the rapid development of computer models of human action: Rewards are high for developing naturalistic, computer-generated visible speech, driven by a real actor's voice or from text (*see* http://mambo.ucsc.edu; Stork and Henneke, 1996; Massaro, 1998; Massaro *et al.*, in press). From the speech-perception point of view, non-acoustic aspects of the speech signal need to be considered in order to develop adequate models of natural speech comprehension. The variability in the signal that arrives at the listener's ears is a problem for a purely acoustic perceptual system. Does adding the talker's face and body improve the reliability of such analysis, and if so, how? In another realm, that of hearing loss and hearing remediation, and especially cochlear implant development, seeing the speaker's speech is a critical determinant of the ease and utility of hearing-aid use (see Bergeson and Pisoni, 2004, for review of this field).

A key finding, which reinvigorated the study of audiovisual speech processing, was that of McGurk and MacDonald (1976), who demonstrated that a heard syllable, presented in a quiet setting, could be influenced by a face that appeared to be saying something else. They showed that seeing 'ga' while hearing 'ba' led to the impression that 'da' had been spoken. This effect was not a unique demonstration of the influence of vision on audition, but it was the first time that the phenomenal report of a heard speech sound was categorically different depending on whether the eyes of the perceiver were opened or closed. The effect is powerful, robust, and relatively automatic. It can be demonstrated in children. The underlying mechanism is not difficult to unpick in general terms: 'ba,' 'ga,' and 'da' are acoustically similar, differing in terms of spectral features that are easily lost in noise. By contrast, the visible distinction between 'ba' (lips closed for the initial consonantal plosive) and 'ga/da' (mouth open) is reliable and

observed easily. As long as phonetic features can be derived from more than one modality and are integrated prior to perceptual report, then 'da' is likely to be the best fit to a seen 'ga' coincident with a heard 'ba.'

This demonstration locates one source of audiovisual integration at the segmental (phonemic) level, but prephonemic aspects of speech are sensitive to vision. Four- to five-month-old infants, who have not yet tuned in to the phonetic contrasts of the spoken language that surrounds them, are susceptible to McGurk effects, responding to a speech event as if it were novel when its novelty resides in the audiovisual, but not the auditory percept (see Burnham, 1998). In adults, visual aspects of the talker's speech affect where the perceiver sets phonetic boundaries. Using tokens spliced from videoimages of talkers under different speaking conditions, Green and colleagues showed that seen speech rate and seen place of articulation affect boundaries for perceiving voicing (/p/ vs. /b/), a phonetic feature with the acoustic correlate of voice-onset time. Nor is voicing the only phonetic feature to be affected by vision. The perceived boundary between heard /l/ and /r/ is sensitive to a preceding bilabial ('iri' vs. 'ili' and 'ibri' vs. 'ibli'). That is, the perceptual system adjusts for perceived anticipatory coarticulation. Green and Norrix showed that the shift occurs when /b/ is simply seen in the token, as well as when it is heard (Green, 1998). These demonstrations are unlikely to be unique. They suggest that the phonetic processor is promiscuous with respect to the source of speech information.

Given these fine-grained effects of vision on audition, we should not be too surprised that susceptibility to McGurk effects can be sensitive to the language of the speaker and perceiver, for the phonetic characterizations of languages differ, even when some of the phoneme categories appear superficially to be similar. Sekiyama and colleagues report reduced susceptibility to McGurk effects in Japanese and in Chinese perceivers and also that the effect varies with the appearance of the talker – talkers who appear to be Japanese generate different effects than those who appear to be American (Burnham and Sekiyama, in press). Much detailed work remains to be done on cross-linguistic perception of audiovisual speech. For the moment, studies suggest that skilled language users bring to speech comprehension analysis of both visual and acoustic properties of speech that they know and that these infiltrate processing at the most fine-grained, phonetic level. A similar point can be made with respect to dialectal and idiolectal speech processing. These forms of processing are almost entirely unexplored in relation to sensitivity to audiovisual illusions, but a start has been made. Walker *et al.* (1995) reported that McGurk effects were more likely to occur with unfamiliar than with familiar face-voice combinations. This finding suggests that the highly idiosyncratic specific actions associated with a known individual saying 'da' are well represented in memory and are therefore not so likely to be confused with (seen) 'ga' or (heard) 'ba' uttered by that individual (see also Lander and Bruce, in press).

Perhaps surprisingly, given the fine temporal resolution (tens of milliseconds) required to distinguish many consonantal sounds by ear, classical McGurk effects are not very sensitive to synchronization (McGrath and Summerfield, 1985; Munhall *et al.*, 1996). Visuo-auditory lead times of up to a half-second do not noticeably impair audiovisual integration in running speech (Campbell and Dodd, 1980). Shorter 'windows of synchronization' are required for other bimodal events, such as glass breaking or hands clapping, and such environmental sounds tend not to show asymmetries in favor of vision leading audition. The reasons for these differences are still obscure, but are likely to relate to the visual correlates of anticipatory coarticulation. The disposition of the facial muscles can be set for optimal production of a word, phrase, or even sentence well in advance of the precise movements of the (less visible) speech articulators: For example, in producing the sentences (each with a focus on the last word) 'my mother bought me a tutu' and 'my mother bought me a wee-gee,' the distinction between them can be seen in the extent and shape of mouth opening early in the production of the sentence, and sometimes even at the utterance of the first syllable. The audiovisual speech processor is sensitive to such long-distance visual cues in the speechstream, but is sufficiently flexible to manage well-synchronized fine-grained temporal distinctions as well.

What mechanisms account for McGurk effects? Bernstein *et al.* (2004) offered a recent, authoritative review (see also Schwartz *et al.*, 1998). The main issues are sketched out here. One influential approach (Massaro, 1987; 1998), saw audiovisual speech as a special case of a general integration metric within perception. It supposed that, within each modality, specific perceptual features (in this case phonetic) are identified; these features are then aligned for integration, and a bestfit to a pattern prototype (in this case, a consonantal phoneme) is achieved using Bayesian procedures – a fuzzy logical model of perception (FLMP). This late integration and identification model has powerful generalizability, but hardly characterizes the extent to which audiovisual speech may be special. It also has difficulties in explaining

prephonemic integration, including evidence from prelinguistic infants and audiovisual influences in phonetic categorization mentioned above. In contrast, a late integration model honors one important finding: Auditory adaptation effects, whereby repeated presentations of a spoken syllable shift the perceived phonetic boundary of an aftercoming, ambiguous syllable, are not susceptible to audiovisual (illusory) pressures. That is, there is a level of acoustic speech function that may be inaccessible to visual influence (Roberts and Summerfield, 1981; Saldaña and Rosenblum, 1995).

Other approaches to integration have been more naturalistic. Thus, Rosenblum (Rosenblum and Saldaña, 1998; Rosenblum, 2005) offered an ecological perspective that focused on the attributes of the speech signal – whether heard or seen – that have commonalities of structure. This approach forced a very different view of the speech signal than that which emphasized the complementarity of vision and audition. The latter approach was epitomized at the beginning of this article in the context of phonological identification and can be taken to be a general principle of speech in many different languages: One reason that audiovisual speech is useful is because vision can deliver contrasts that are relatively poorly discriminated by ear. Figure 1 illustrates this point.

However, the complementary process approach begs the important question – exactly how does integration across the modalities occur (the binding problem)? Theoretical approaches that stress commonality of structure across vision and audition offer a feasible (albeit partial) solution to the problem of integration. If the developing child picks up on regularities in the perceived environment – for example, regular changes in amplitude of a noise-emitting object as it approaches and recedes from the perceiver – an amodal processor should be sensitive to (say) time-varying changes in acoustic spectral characteristics and retinal size, each with similar dynamic characteristics and each locked to a common timeline. The relevant information for natural perception should be sought in the stimulus characteristics. Such direct perception notions have a history dating back to J. J. Gibson (1966) in visual perception, whereas in speech perception, they are epitomized by motor theories (Liberman and Mattingly, 1985; Fowler, 2004). The consequences for audiovisual speech were elaborated in a pioneering discussion by Summerfield (1987). This analysis suggested that 'the object of perception' in speech is not a specific acoustic signature, but rather the speech gesture itself, characterized by its motoric, acoustic, visible, and somaesthetic correlates. Speech gestures are intrinsically and essentially dynamic, for speech is produced in real time and is characterized by temporally structured distinctions as it is perceived. However, such characteristics can be picked up by sensors in any of the different modalities. Indeed, it is the exploration of the temporal (time-varying) attributes of seen speech that has

Figure 1 Confusions made among (A) visually perceived and (B) auditorily perceived consonants in CV syllables of vowel sound 'ah.' Easily confused consonants cluster at the top ends of the branches; least confusable consonants are at the roots. (A) summarizes the results of a cluster analysis of the visual confusions made by trained hearing-impaired adult observers. The pattern is roughly the reverse of that in (B), which is derived from auditory confusions made in different levels of auditory noise (more noise, lower horizontal lines). For example, 'm' and 'n' are not confusable visually, but are confusable auditorily (within the solid markers), whereas 'p' and 'b' are confusable visually, but distinguishable auditorily (within the dotted markers). Adapted from Summerfield (1987).

produced some of the most impressive recent experimental data. Rosenblum and colleagues have shown that McGurk effects can be induced when the perceiver sees speech illuminated solely by point-light movements on the facial surface – that is, when no detail of the visual form of the disposition of the articulators at a particular point in time is available (*see* http://www.faculty.ucr.edu for demonstrations). Munhall, Vatikiotis-Bateson, and colleagues (see Munhall and Vatikiotis-Bateson, 1998; Munhall *et al.*, in press) encompassed insights from motor-theoretical approaches into a different program. They attempted a detailed, engineered, description of natural speech in terms of its motor, acoustic, and visible properties, along with the requisite computational algorithms for producing and perceiving it. This work has underlined the importance of visible speech kinematics beyond the phoneme or syllable. For example, one recent study showed that seeing the head movements of the talker improved intelligibility of auditory speech-in-noise in passages of connected speech. In particular, larger head movements correlated with both voice frequency (F0) and acoustic amplitude (Munhall *et al.*, 2003). **Figure 2** shows how this correlation can be demonstrated. Aspects of the acoustic spectrum and temporally aligned head movements as measured by optical tracking devices mounted on the head and face show clear correspondences.

The finding (Kamachi *et al.*, 2003; Lachs and Pisoni, 2004) that different (unknown) individuals can be identified cross-modally from their vocal patterns at better than chance levels suggests a similar 'correspondence-seeking' process at work, but here it works in the service of identification of the talker, rather than the content or intent of their speech. These studies have shown that identifying a particular talker (audio-only) after watching a number of people talk (vision only) is possible, even when the talkers are similar in age, gender, and other obvious characteristics that might affect perceived voice quality. The reverse is also possible. Identifying a particular talker (vision only) after hearing how he or she speaks can be performed at above chance levels. Control experiments suggested that the characteristic speech patterns of the talker are the basis for this ability, although the detailed cues required to make this identification are still unknown. In Kamachi's study, for instance, neither still photographs of a talker nor reversed-animation images of the talker were matchable to the heard voices. To drive the point home, Lachs and Pisoni (2004) found that point-light versions of the talker's face, with no further image detail

Figure 2 Example of acoustic and head-movement patterns for a single sentence (A) and results of the multiple regression analyses (B, C). In (A), the acoustic waveform, fundamental frequency of the voice (F0), and six degrees of freedom of head motion (three positional coordinates: x, y, z; three angular coordinates: roll, pitch, yaw) are plotted as a function of time. (B) shows the R^2 values for the multiple regression analysis of F0. The correlations are consistently high, with on average more than 63% of the variance in the talker's voice pitch being accounted for by the six components of head motion. (C) shows R^2 values as predicted by the six degrees of freedom of head motion, plotted for the 20 sentences used as stimuli. Although the correlations are smaller than for F0 (mean $R^2 = 0.324$), they are still strong for most sentences. From Munhall K G *et al.* (2003), **Figure 2**, with permission of Blackwell (publishers), and the author.

(no shape of the mouth or size of the teeth), could support such identity matching.

Brain Bases for Audiovisual Speech Processing

Although the brain bases for language have been well researched for 150 years (*see*), studies of the cortical bases for McGurk effects were initiated by Sams in 1991 (Sams and Levänen, 1996) and are ongoing using ERP and MEG techniques (for example, Colin *et al*., 2002; Raij and Jousmäki, 2004). These studies suggested that the visual component of an audiovisual percept can affect left temporal regions that are specifically active when listening to speech, within 180–220 msec of stimulus onset. This relatively early waveform can be distinguished from a later modulation of the auditory waveform that can occur for less 'natural' cross-modal pairings, such as a letter and its spoken name (see Raij and Jousmäki, 2004, for review). MEG and such similar procedures as ERP have fine temporal resolution, but for spatial resolution, PET and fMRI are preferred options. Using fMRI, Calvert *et al*. (1997) showed that several sites within the superior temporal lobe were preferentially activated by audiovisual speech. These sites included the auditory cortex, including some lateral parts of the primary auditory cortex on the edge of Heschl's gyrus, and the secondary auditory cortex in the surrounding superior temporal plane and extending into the superior temporal gyrus on the lateral surface of the temporal lobe. Within visual regions, extensive activation was observed in inferior occipito-temporal sites (Brodmann areas 37/39), regions characterized as responsive to visual movement.

Neuropsychological case studies confirm the importance of visual movement analysis to audiovisual speech perception (Campbell *et al*., 1997; Munhall *et al*., 2002). A region that appears to be especially implicated in audiovisual speech is the posterior part of the superior temporal sulcus (STS), on the inferior surface of the superior temporal gyrus. This region has been proposed as an essential binding site for auditory input (via the secondary auditory cortex) and visual input (via secondary visual regions), because it is in this region that activation for bimodal processing is nonlinear and usually super-additive, with respect to each of the unimodal processing patterns (Bernstein *et al*., 2004; Calvert and Lewis, 2004; Campbell *et al*., in press). The temporal course of audiovisual speech interaction, measured using MEG, also supports this proposal (Möttönen *et al*., 2004).

Does activation within the STS thus reflect binding of the complementary features of audition and vision (see Figure 1), or is the STS essentially a detector of commonalities of seen and heard speech, especially in terms of its temporal signature? A suggestion that brain sites can be distinguished that support these different functions is emerging. Callan *et al*. (2004) used spatial wavelet-filtering techniques to degrade visual information in audiovisual processing. Low-filtered information retained movement information, but lost much of the fine (visual) spectral information required to identify the place of articulation. In contrast to a low-filtered condition, high-filtered and unfiltered audiovisual clips activated the (left) middle temporal gyrus (MTG, BA 21), as well as the superior temporal gyrus. One inference is that the MTG is especially implicated in the processing of the visually perceived place of articulation.

Brain imaging studies also seem to support the notion that gestural aspects of speech are integrated into its perception. The production of speech is generally associated with activation in left frontal regions, with the left inferior frontal regions as a critical focus (Broca's area = Brodmann areas 45/47). Not only is Broca's area regularly activated by audiovisual speech perception (Callan *et al*., 2003; Campbell *et al*., in press) but transcranial magnetic stimulation on the skull above motor regions of the brain (left frontal regions) also causes electromyographic activity of the lips and tongue to be blocked when watching audiovisual speech (Watkins *et al*., 2003). The location of the sites currently known to be involved in audiovisual speech perception is shown in Figure 3.

Audiovisual Speech: Detection and Attention

The focus on McGurk effects detracts from some other interesting aspects of audiovisual speech. Grant and Seitz (2000) asked whether seeing the speaker helps in detecting as well as identifying speech in noise. The detection of speech-in-noise is an acute practical problem for a range of communication systems. Using spoken sentences presented sparsely, in large amounts of white noise, they found a mean audiovisual-to-auditory advantage to sentence detection of between 1.0–2.2 db, depending on the sentences seen. This advantage was specific to audiovisually concordant sentences: There was no advantage in detecting sentences when the face and voice did not match. However, Schwartz *et al*. (2004) showed that the effect of vision on auditory speech detection in high levels of noise is not specific to the detailed facial movement information in the face. A facial animation display of an ambiguous syllable was sufficient to cue syllable-specific auditory signal

Figure 3 The left surface of the brain, lateral view. Regions shown in dark gray have been implicated in visual (speechreading) and audiovisual speech perception. STS = superior temporal sulcus, MTG = middle temporal gyrus.

processing. This general 'alerting' aspect of visual speech brings to mind the ventriloquism illusion (Radeau and Bertelson, 1978), whereby a heard sound is perceived to originate from a seen source that may be distant from it. A more complex version of this effect was demonstrated by Driver (1996) who showed, using spatially and temporally overlapping voices with seen-to-be-speaking faces at different locations, that preattentive cross-modal matching occurs. Under these circumstances, the perceiver can shadow one of the overlapping voices better when the two speech events appear to originate from spatially separated speaking faces, with each one being congruent with one of the auditory speech tracks.

However, visual enhancement of the detection of speech-in-noise is not just a function of speech-universal, general-purpose alerting mechanisms based on general familiarity with the visual correlates of speech. Kim and Davis (2003) found language-specific enhancement in a sentence-in-noise detection task when they contrasted Korean and English participants in their own and the other language. This enhancement occurred only for sentences that showed low correlations between acoustic temporal envelope spectral characteristics and visual articulation movement. For sentences where the correlation was high, other-language users were worse at detecting sentences in audiovisual than auditory conditions. One suspects that detection-in-noise involves the activation of relatively high-level, language-specific processes, even in the absence of full identification of the material, but the reasons for this paradoxical effect remain to be clarified.

Conclusion

Several issues have been highlighted in this short and selective review: To what extent does audiovisual speech depend on mechanisms that reflect correspondence between input systems, or on those mechanisms that reflect complementary between them? To what extent do top-down and bottom-up mechanisms, and the processing of visual movement, affect the variety of audiovisual phenomena touched on in this article? It has not been possible to do more than give the flavor of a burgeoning area of research, one that is developing from a growing and well-defined community of cross-disciplinary researchers. Its growth in recent years may be technology led – Digital processing has made possible explorations that were hardly dreamt of even 10 years ago – but it has a scientific core. Respecting the signal and sensory properties of speech in the auditory and the visual domains means that theories of how speech is acquired and used will be placed appropriately in their biological and computational context – one in which the perception of speech may be acoustically dominant but not all-powerful and one that needs to encompass vision, action, and bodily sensation.

Augmentative and Alternative Communication

N Alm, University of Dundee, Dundee, UK

What is Augmentative and Alternative Communication (AAC)?

Augmentative and alternative communication (AAC) refers to methods of communication that can supplement speech and writing when these are impaired. When a disability makes it impossible to use speech as the primary means of communication, other techniques must be employed. The central importance of communication for human beings has meant that a wide variety of imaginative augmentative and alternative approaches has been developed. Often some ability is still present to communicate naturally, and this is usually employed as much as possible. Users of special communication methods will often continue to make use of vocalization, facial expression, and gesture, to the degree they are possible, along with their alternative methods of communication. Unimpaired communication is, of course, inherently multimodal, with the speech content being modified by prosody and delivered in parallel with facial expression, gesture, posture, and a range of other nonverbal communication methods. Both unaided speakers and augmented speakers will use multiple communication modes simultaneously, but the augmented speaker must use a variety of special techniques to compensate for their physical impairment. The ultimate goal of AAC is to help users accomplish the full range of human interactions, which involves information transfer and the expression of needs, but more importantly also includes performing social routines and maintaining social bonds.

There are times when everyone may make use of alternative methods of communication. For the unaided speaker, this is typically when the environment makes the usual forms of communication difficult. We may use gesture and iconic hand signals to communicate at a distance across a noisy room; or, at a lecture we may give an exaggerated facial expression to silently signal an opinion to a friend sitting next to us. Special techniques developed by people with disabilities can be seen as ways to help a disabled person deal with the ordinary environment; interestingly, the same or similar approaches are often used by the ordinary person who is temporarily disabled by the environment in which they find themselves.

Who Uses AAC?

The inability to communicate without some sort of assistance can have a number of congenital or acquired causes. The most common congenital causes

Augmentative and Alternative Communication

N Alm, University of Dundee, Dundee, UK

© 2006 Elsevier Ltd. All rights reserved.

What is Augmentative and Alternative Communication (AAC)?

Augmentative and alternative communication (AAC) refers to methods of communication that can supplement speech and writing when these are impaired. When a disability makes it impossible to use speech as the primary means of communication, other techniques must be employed. The central importance of communication for human beings has meant that a wide variety of imaginative augmentative and alternative approaches has been developed. Often some ability is still present to communicate naturally, and this is usually employed as much as possible. Users of special communication methods will often continue to make use of vocalization, facial expression, and gesture, to the degree they are possible, along with their alternative methods of communication. Unimpaired communication is, of course, inherently multimodal, with the speech content being modified by prosody and delivered in parallel with facial expression, gesture, posture, and a range of other nonverbal communication methods. Both unaided speakers and augmented speakers will use multiple communication modes simultaneously, but the augmented speaker must use a variety of special techniques to compensate for their physical impairment. The ultimate goal of AAC is to help users accomplish the full range of human interactions, which involves information transfer and the expression of needs, but more importantly also includes performing social routines and maintaining social bonds.

There are times when everyone may make use of alternative methods of communication. For the unaided speaker, this is typically when the environment makes the usual forms of communication difficult. We may use gesture and iconic hand signals to communicate at a distance across a noisy room; or, at a lecture we may give an exaggerated facial expression to silently signal an opinion to a friend sitting next to us. Special techniques developed by people with disabilities can be seen as ways to help a disabled person deal with the ordinary environment; interestingly, the same or similar approaches are often used by the ordinary person who is temporarily disabled by the environment in which they find themselves.

Who Uses AAC?

The inability to communicate without some sort of assistance can have a number of congenital or acquired causes. The most common congenital causes

are cerebral palsy (usually produced by brain damage at birth), developmental delays, specific language disorders, and autism. The most common acquired conditions among people who use AAC are amyotrophic lateral sclerosis (ALS – also called motor neurone disease in the U.K. and Lou Gehrig's disease in the United States), multiple sclerosis, head or spinal cord injury, and stroke. Estimates of the prevalence of the need for AAC vary, but a figure of about 0.1% of the population is frequently cited. Of course, manual signing systems have been developed for deaf people, and these constitute a rich and efficient language system. People with learning difficulties may use simple manual signing systems as well as graphic symbols to assist in communication. The AAC systems described here are primarily used by people whose difficulty consists of impairment in the physical systems that produce vocal communication.

Types of AAC

AAC constitutes a spectrum of methods used to communicate, from techniques which require no equipment at all to methods using cards, boards, and books, to systems making use of advanced technology. A typical AAC user will employ a number of techniques in parallel and will vary the technique used depending on the situation and with whom they are communicating. Roughly speaking, the use of specialist materials and techniques is more and more appropriate as the user communicates with people they do not know well. One approach may be used at home, a second when with friends, and a third with strangers.

Despite a lack of intelligible speech, vocalization can still be useful for many nonspeaking people. If a vocal sound of any sort can be produced, it can be useful to signal assent, disagreement, or understanding, or to convey an emotional reaction. Most communicators with AAC like to make use of as much voice as they can in their communication. Pointing can also be used, for instance, to make a referent clear. For people who are unable to move, except for their eyes, the eyes may be used to indicate rough direction. Facial expression and gesture can be employed to the degree that the person is able to control their movements. One problem that a person with lack of muscle control can have is that the facial expression may not accurately reflect their communicative intention, and can be misinterpreted by people not familiar with them. With family and close friends, however, this mode of expression is still usable to some extent. Signing systems may be of limited use to some nonspeaking people who also have a physical disability. Having said that, many people have developed a set of personal gestures that they can use with those who are familiar with them. Also, as has been noted, for people who have communication difficulties but retain good muscle control, such as some people with learning difficulties or developmental delays, sign language can be a useful precursor and then a support for verbal communication, or it may be a good permanent augmentative strategy.

A number of methods have been developed to help nonspeaking people communicate using graphic symbols and text. For people who have a learning disability along with their speech difficulty, actual objects can be used to assist in communication. The user can point to boards or cards with graphic symbols, letters, or text in order to convey their message. Where the user is unable to point, eyegaze direction is sometimes used with a large board. Another technique is for a helper to go through the options on the board, with the nonspeaking person indicating their choice by whatever method they can manage. With some progressive conditions, a controlled eyeblinking ability is retained even when all other voluntary muscle functions are not operating. This capacity can be used as part of the signaling system for a helper.

Communication boards or booklets can display pictures, graphic symbols, letters, words, or phrases. Pictures are the most particular in their reference, graphic symbols are more general than pictures, and text provides the most flexibility in expression. The expressive power of the method must be weighed against the linguistic abilities of the user. One relevant consideration is that a high percentage of those born without the ability to speak struggle to achieve literacy, which is independent of their intellectual ability. Thus even those with an adult level capacity of expression and understanding may require a graphic symbol system for communication, rather than one requiring spelling and grammatical abilities. A number of graphic symbol systems are currently in use, of varying degrees of abstractness. A system called Blissymbolics is a graphic symbol language with its own syntax. This was originally developed as a suggested method for cross-language communication. The structure of the symbols is modeled on Chinese characters, with a central meaning component that can be concatenated with other subcomponents to modify the meaning. Blissymbols provide a richer form of communication than systems consisting of single, unmodifiable graphic symbols, but they require that the communication partner also be familiar with them. Adding ordinary text labels to Blissymbols, and other graphic symbols sets, makes them more universally useful.

Using graphic symbol systems, and indeed any AAC method which provides a partial version of a

full grammatical utterance, puts more of the responsibility for successful communication onto the communication partner, compared to conversations between unaided speakers. The development of electronic and computer-based communication systems has the potential to redress this imbalance somewhat. However, what has emerged is that the issue is a complex one. Communication between people is in fact a system involving all participants simultaneously, and not just a case of active speaker and passive listener swapping roles. The usual conversational rule is that participants expect to bear an equal responsibility for the success of the communicative encounter. From the point of view of a conversation partner who has natural speech, interacting with a person using AAC often requires extra effort from them to interpret abbreviated utterances. Often the communicative process that emerges from an encounter between someone using AAC and a naturally speaking partner is one that encourages passivity on the part of the person using AAC. Improved technologies offer them ways to take more control of an interaction, but they do require the user's attention to be diverted from the conversation partner and focused on the technology that is helping to construct the utterance. This disruption of the intimacy of an encounter is often felt to be so unhelpful as to make the increased communicative independence not worth the effort. Research continues on ways to make the technology less obtrusive in an interaction, but this issue remains as an important one on the field and illustrates the blend of technology and social aspects that characterize improvements in AAC.

Speech Synthesis

The development of good quality synthetic speech would seem to offer nonspeaking people the possibility of having or regaining a voice. However most nonspeaking people have physical impairments that, as well as denying them naturally produced speech, also impede their rapid use of any controlling mechanisms for synthetic speech. The rate of speech output would need to be extremely high to keep up with normal conversational rates, which range from 120 to 200 words per minute. Nonetheless, the availability of intelligible and acceptably human-sounding synthetic speech has made a great difference to nonspeaking people.

Natural speech can be recorded and stored in a computer system. A wide number of portable devices are available which can store common words and phrases for outputting when needed. Synthetically created speech offers greater flexibility; new words and phrases can be produced at will. To accomplish this, the system must perform a conversion of text into synthetic speech.

Two approaches to creating synthetic speech are by using rules, and by the use of statistical methods with a corpus. A rule-based system employs rules and heuristics derived from theoretical and empirical work in phonetics. Rule-based speech synthesis has achieved good intelligibility and a reasonable level of naturalness. However, in common with rule-based approaches in artificial intelligence, such systems are heavily reliant on complex sets of rules and parameters, which tend to be particular to the individual system, and are not easily shared across systems. The corpus-based approach involves sets of coded speech data which are used as the basis for a statistical approach to building a model. The corpus-based approach is currently seen as the most promising for future development.

The quality of speech synthesis is usually judged in terms of intelligibility and naturalness. Intelligibility can be measured, but naturalness is a more subjective quality. Most agree that it would include prosodic features that convey expressive features along with the information content. With a natural speaker, there will be an emotional overlay to the words spoken, individual speaking style, and features that relate to the nature of the communicative event. Work continues on increasing the perceived naturalness of synthetic speech. It may be that taking a selective, more 'impressionistic' approach to the problem offers a better solution than attempting to exhaustively mimic all the details of natural speech.

Electronic Assistance

The development of speech synthesis and of smaller, more powerful electronic devices has made possible the presentation of communication boards in electronic form, with speech output. A number of specialized input methods have also been developed, so that users can direct the communication system by activating it with a finger, thumb, hand, fist, head, foot, eyeblink, and in fact any part of the body with which the user retains good control. For people who have good muscle control, the direct selection of language units is possible. Where muscle control is more limited, a scanning technique is used, with candidate choices presented and the user indicating their selection with a single switch activation. In order to make the scanning process more efficient, ways have been sought to devise scanning methods that minimize the time taken to make a selection. Row/column scanning involves working with a grid display, selecting from a row and then a column, thus homing in on the wanted item. Scanning layouts are

usually organized with most frequently needed items at the start of the scan. A binary selection technique can be employed, which involves the user selecting which half of a set of displayed items contains the one they want. A sequence of such binary selections homes in quickly on a desired item, even in a large set. For people with a visual impairment, auditory scanning can be employed, with the candidate selections voiced by synthetic speech.

Computer-Based Assistance

Computer-based AAC systems are now widely used. These include dedicated systems, where the hardware and software are part of the one package, and software-only systems that can be run on any personal computer. In both cases, hosting an AAC system on a computer allows for a number of assistive methods for the user to be provided.

The control display can be a dynamic one. An interesting issue about dynamic displays is that there is a trade-off between speed of access and familiarity. For instance, it is possible to rearrange the items on a grid of selections based on the choice made thus far. Users often report that they would prefer to leave the choices in a set position, which they become familiar with, rather than have to hunt for them in a new configuration, even if it is a smaller one. This issue highlights one of the difficulties faced by people using AAC. Natural speakers, talking at 120–200 words per minute, do not need to be consciously aware of the details of how they are selecting and arranging their vocabulary. Indeed, this would not be possible, given the speed of the output. The person using AAC, however, because of physical difficulties causing a reduced speed of communication, is by the nature of the process consciously aware of the details of the communication construction. Because of this, AAC might be characterized as more like a written than a spoken communication mode.

The way that language material is laid out on a dynamic display can vary, and with most systems the user can choose the layout that best suits them. The material is often presented in way that reflects both the semantics and the pragmatics of communication. A semantic approach might involve a taxonomic classification of items, organized in a tree structure. Pragmatics-based schemes include organizing material for quick output of social greetings, feedback remarks, and farewells, and putting together 'pages' of material suitable for particular tasks or situations. Frequency of use can be tracked, and this information can be used to place material higher in a hierarchy of possible choices (though attention must be paid to the speed–familiarity trade-off referred to earlier).

For users who are able to construct text, a number of predictive word-completion systems have been developed and are in common use. These tend to make use of frequency-tagged dictionaries in order to offer the user a short menu of predictions as to the word being created. Some systems also include a 'recency' factor that has the effect of upgrading the rating of uncommon words that the user employs, at least for that session. This can have the effect of capturing context words for that particular conversation. Thus if a relatively infrequent word, such as *elephant* is used, it will come up high on the prediction list the next time an *e* is typed in to begin a word. Attempts have also been made to include syntactic information to improve word completion. These have offered only a slight improvement in performance, but some users have reported valuing the way that such a system will not present them with clearly inappropriate words. One consideration with word completion systems is that the user must pay attention to the prediction menu, as well as continuing to type in their text. This means that such systems tend to be used only by people whose typing is so slow that the cognitive overload problem is not an important consideration. Another method of accelerating input is to predict word pairs, based on tracking the user's previous utterances. Here the payoff for glancing at the prediction list could be considerable if the second word is a long one.

Coding systems have been devised to allow users easier access to common phrases and words. One technique is to take the first letter of each word in a phrase to make a short sequence of characters that can retrieve the whole phrase. A very successful input acceleration technique has been developed that enables users to retrieve words by using a sequence of multimeaning icons. The first icon in the sequence sets the context for the next ones. For this to be effective, users must memorize the icon sequences for a large dictionary of words, but having done so, they can regain to a degree the sense of communication flow without the deliberation that natural speakers experience.

As has been said, a typical person using AAC will employ multiple modes of communication in parallel. It may be that people unfamiliar with them will only be able to understand speech output from a computer-based AAC system, but the more familiar conversation partners will be able to interpret a range of communicative acts.

Research into Improving AAC

While many users of AAC have put a great deal of effort into mastering what are at best cumbersome

ways to enable them to interact through language, the slow communication rate of even the most advanced AAC systems used by the most skilled operators reduces the ability to interact fully. It is a common experience for AAC users that their slow response time means the conversation has moved on to a new topic before they can make their contribution. Also, when they have a speaking turn, the conversation must step down to a much slower pace, which makes many unfamiliar participants uncomfortable. In order to keep up as far as possible with the rapid speed of interaction going on around them, many AAC users must often confine themselves to single word utterances.

Research continues on finding ways around this problem. There is a debate underlying this about the importance of communication rate as opposed to communication effectiveness. Arguing from a systems point of view, many say that the communication of an individual using AAC cannot be measured in isolation: the communicative approach of the other participants plays a part. This is undoubtedly true, and a trained or familiar partner can greatly increase the communicative effectiveness of the person using AAC by helpful techniques and attitudes. However, what is unavoidable is that when it comes to very low communication rates, quantity must affect quality in most situations that they will encounter.

In an attempt to help users who have physical limitations that restrict their movement so that using a normal keyboard is not possible, large-format touchpad keyboards are available. Work has also been done on having reduced-key keyboards with multiple letters assigned to each key. Software has been designed that disambiguates the text that is being typed in, by making use of transition probabilities for the possible sequences that the keys could produce. The probabilities are derived from text corpuses. It has been established that this can be effective, even starting with a relatively small corpus and an adaptive capability. One example of a reduced-key keyboard is of course a telephone keypad, and when texting on a mobile phone, users can make use of disambiguation software provided by a number of manufacturers. This is a recent but not by any means the only example of work originally done for people with disabilities having a general application. As has been noted, the reason this works is that all of us may at different times have a temporary disability, in this case, having to cope with a smaller than normal keyboard because of space restrictions on the mobile phone and the size of our fingers.

Another form of reduced input that has been explored is allowing the user to enter a few letters, and from this predicting the correct word, then allowing them to enter a few words, and from this predicting the correct sentence. The technique involves a semantic analysis of the input and the generation of syntactically correct output using a functional unification model. This is a computationally expensive approach, but may point out a useful direction for future systems.

The reason that people using AAC produce utterances at such a slow rate is that they must put them together letter by letter, or word by word, unlike natural speakers who can take advantage of the rapid, largely unconscious control of the speech organs. The subjective experience of a natural speaker is that of thoughts and intentions materializing into speech almost magically, so that they are sometimes surprised by what they say themselves. In an attempt to mimic this practically effortless move from thought to utterance, some systems have been developed for whole-utterance communication, which consist of a large amount of prestored conversational material and a method for predicting when particular items will be needed.

This approach involves applying knowledge from the pragmatics of communication, and in particular, findings from discourse and conversation analysis, to highlight areas of communication which might be amenable to this sort of prepackaging. Work has been done on stereotypical aspects of communication, such as openings, closings, and feedback remarks. Systems have been developed for transactional communication based on scripts and frames. Coping with specific situations such as shopping and talking on the telephone can be catered for more easily than for just chatting. However, more free-flowing, casual conversation has been modeled in prototype systems by means of intersecting perspectives of time and aspect, and by using fuzzy information retrieval.

The increasing power and decreasing size of computers with multimedia capability has offered new possibilities for people using AAC. It may be that having to communicate by computer could offer advantages that natural speakers do not enjoy, in the form of being able to show graphics, photos, and film, and employ sound effects and music as part of an interaction. This possibility remains a research speculation at the moment. One factor that will militate against this is the usual wish to reduce the prominence of the technology between the person using AAC and their conversation partners, in order to maximize the interpersonal impact of the interaction. As with all the technical approaches to AAC, their introduction will only work when they add real value to the communicative interaction and do not require too much of the users' time and attention to be diverted from maintaining rapport with the other

participants and enjoying a meaningful interaction. Smaller and smaller devices offer the possibility of the kind of unobtrusive help that is wanted by nonspeaking people, but there is a significant design challenge in creating an interface on such a small display that is both efficient and effective.

The AAC field is an unusual one, in that it is not just clinicians or researchers who are creating improvements and increasing our knowledge. People using AAC, their families, and manufacturers of AAC systems all provide input to the process of improvement and widening understanding of the field. This is reflected in the membership of the international organization that promotes AAC. The International Society for Augmentative and Alternative Communication (ISAAC) has members from the whole spectrum of involvement in AAC, and its international conferences draw participation from all these groups.

Augustine, Saint: Theory of the Sign

J Deely, University of St Thomas, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The Augustine treated in this article was born in 354 A.D. and died in 430 A.D. No man or woman has left a larger mark on intellectual culture, both that of his own Latin times and after. His seminal contribution to the theory of the sign is a good example of why. "Symbols grow," Peirce noted; and Augustine in the matter of signs symbolizes nothing less than what we might properly call the original florescence of semiotic consciousness.

Before the work of Augustine, signs were conceived of as a particular class of natural events, to wit (Aristotle, *Prior Analytics* II: Chap. 27, 70a8), "anything such that when it is another thing is, or when it has come into being the other has come into being before or after, is a sign of the other's being or having come into being. In the intellectual culture of ancient Greece, medicine had come into being on the basis of this notion of sign as σημείον. And in general, 'signs,' σημεία, were the basis on which human beings depended for understanding the world of nature, sickness, and health, events providing the basis for inferences about what is, has been, or will be.

Of course, to understand nature, to predict a storm or diagnose an illness, words will be necessary among humans. But they were seen as quite external to **what it was** that was being predicted or diagnosed, far removed from it, and belonging to another realm entirely. The realm of φυσις, or nature, was one thing, quite another was νομοσ, the realm of human creations and language, σύμβολα and ονοματα. Human language in particular, for us today a realm of signs *par excellence*, no one in the ancient world conceived in terms of 'signs.' At most, for particular rhetorical and logical contexts in which inferences concerning σημεία were at stake, the idea of words as signs would come up indirectly. No one denied that words were signs. But neither did anyone carry on any reflection about language in general in terms of signs.

Augustine, Saint: Theory of the Sign

J Deely, University of St Thomas, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The Augustine treated in this article was born in 354 A.D. and died in 430 A.D. No man or woman has left a larger mark on intellectual culture, both that of his own Latin times and after. His seminal contribution to the theory of the sign is a good example of why. "Symbols grow," Peirce noted; and Augustine in the matter of signs symbolizes nothing less than what we might properly call the original florescence of semiotic consciousness.

Before the work of Augustine, signs were conceived of as a particular class of natural events, to wit (Aristotle, *Prior Analytics* II: Chap. 27, 70a8), "anything such that when it is another thing is, or when it has come into being the other has come into being before or after, is a sign of the other's being or having come into being. In the intellectual culture of ancient Greece, medicine had come into being on the basis of this notion of sign as σημείον. And in general, 'signs,' σημεία, were the basis on which human beings depended for understanding the world of nature, sickness, and health, events providing the basis for inferences about what is, has been, or will be.

Of course, to understand nature, to predict a storm or diagnose an illness, words will be necessary among humans. But they were seen as quite external to **what it was** that was being predicted or diagnosed, far removed from it, and belonging to another realm entirely. The realm of φυσις, or nature, was one thing, quite another was νομοσ, the realm of human creations and language, σύμβολα and ονοματα. Human language in particular, for us today a realm of signs *par excellence*, no one in the ancient world conceived in terms of 'signs.' At most, for particular rhetorical and logical contexts in which inferences concerning σημεία were at stake, the idea of words as signs would come up indirectly. No one denied that words were signs. But neither did anyone carry on any reflection about language in general in terms of signs.

Signs were not 'generals.' They were a particular class of natural phenomena, those phenomena that allow something else to be inferred.

That is the situation that the work of Augustine changed, in particular with his little work titled *De Doctrina Christiana*, begun in 396 A.D. and completed as far as Book III, Para. 35, in 397; then fully finished through Book IV in 427 A.D. (the entire work consists of a Prologue of nine paragraphs, Book I with 44 paragraphs, Book II 63 paragraphs, Book III 56 paragraphs, Book IV 64 paragraphs, covering 167 pages in the critical Martin edition). The heart of his revolution occupies very little space: Book II, Para. 1–5; in particular: Para. 1, lines 5–7; Para. 2, lines 1–3, and Para. 3, lines 1–3. Let us take the texts in turn.

First comes his proposal of sign as a general notion: "Signum est enim res praeter speciem, quam ingerit sensibus, aliud aliquid ex se faciens in cogitationem venire." (For a sign is a thing which, besides the impression it makes on the senses, makes something other than itself come into the awareness.) With this definition, in a stroke, Augustine proposes the sign as superior to the division of being into natural and cultural: any material structure, whether from nature or art, which, on being perceived, conveys thought to something besides itself functions as a sign. There is an earlier work of disputed authenticity but probably of Augustine, written *ca.* 387 A.D. under the title *De Dialectica*, which defines sign in almost the same terms: "anything which shows itself first to the sense and then indicates something beyond itself to the mind." We will discuss shortly the weakness his successors were to divine in Augustine's general formula for sign, but first we need to grasp what was revolutionary about it.

Then comes his proposed division of this general notion: "Signorum igitur alia sunt naturalia, alia data." (Of signs therefore some are natural, others are deliberate), continuing: (The natural signs are those which, independently of any will or desire of signifying beyond themselves, yet make something other than themselves be known," and here we clearly recognize the σημεία of Aristotle and Hippocrates. The explication of the next division is what begins a whole new era of philosophical reflection – the Latin Age as an indigenous development of philosophy in contrast to the Greco-Roman heritage of antiquity.

'Signa data' is usually rendered into English as 'conventional signs.' However, this rendering does not convey the whole idea. Conventional signs are 'man-made,' to be sure, and this is an essential part of Augustine's meaning here, but not the whole essence. 'Signa' that are 'data,' he tells us, are "those signs which living things **of whatever kind** give to one another in order to manifest, **insofar as they are able**, a movement of their soul or sensed or understood things of whatever sort." So 'signa data' are signs deliberately made for the very purpose of communicating. Among these signs, as far as human beings are concerned, the predominant ones are words, the very words of language never before thematically considered under the rubric of sign. To these, Augustine now gives the focus of his intention, both because human beings principally communicate among themselves through words and because through words God has manifested his will for humanity in the books of Scripture.

But rather than follow Augustine down the particular path that he has introduced the general notion of sign in order to locate, let us instead pause at the outset to scan the vista itself that he has opened. Conventional signs are indeed *signa data* as Augustine has defined the expression, but how far they are from occupying the whole of the prospective range of the *signa data*! Augustine proposes a tripartite rationale according to which *signa data* might be emitted: a disturbance of the soul, something sensed, something understood. Keep in mind that the notion of 'anima' or soul in Augustine's time meant not only the human mind (the 'intellectual soul'), but also the life-principle of plants (the soul simply, or vegetative soul), and the principle of animal life as cognitive (the 'sensitive soul'). *Signa data*, then, would include all those actions of signs that are labeled today as 'phytosemiotic,' such as the immune reactions developed by trees a mile or more distant from a tree that suffers an infection ('motus animi sui') or the deceptive forms plants assume to attract particular insects. *Signa data* would also include those actions of signs that are labeled today 'zoösemiotic,' the realm of animal communication with no involvement of words. And only finally would *signa data* involve those actions of signs that are linguistic and species-specifically human, written and spoken language, which we now know presuppose and in various measures depend upon phytosemiotic and zoösemiotic sign activity (Deely, 1980).

The inclusion of natural signs as a coordinate species with the *signa data* under the genus *signum* precludes in principle the later misunderstandings of certain thinkers who, realizing that Augustine was the first to bring language thematically under the rubric of sign, tried to argue that Augustine also opened the path to the late modern semiological conception of sign as *paradigmatically* linguistic, such as was envisioned by Ferdinand de Saussure (1916) and by the intellectual movement of the 20th century known as semiology that developed on the basis of Saussure's proposal. For the natural signs have

nothing to do with human conventions. If, for centuries, from Aristotle to Galileo and after, the philosophers and the Churchmen misread the movements of the heavens to see in them certain indications that the sun revolved around the earth, this misreading did not determine the nature of the case. Through all the misreadings, the independence of the natural movements involved constantly provided the possibility – eventually seized upon, as the web of human experience grew large enough to manifest within itself the truth of those natural connections – of discovering that, all previous opinions to the contrary notwithstanding (including certain literal readings of Sacred Scripture), the earth that revolves relative to the sun and not vice-versa. The Augustinian 'natural signs,' thus, leave wide open the whole question of an action of signs prior to and independent of life in nature at large, or physiosemiotics, as Nöth's symposium (2001) expressly considered.

To appreciate better the vista Augustine has opened, and its independence of his apologetic intentions throughout the work, let us go back to the beginning of his *De Doctrina Christiana*, Book I, Para. 2, lines 1–2, where again he introduces a formula that will prove to reach far beyond his own intentions and understanding of the matter. "Omnis doctrina vel rerum est vel signorum, sed res per signa discuntur." (All doctrine concerns either things or signs, but things are learned through signs.)

Augustine's general theory of signs, as Darrell Jackson well noted (1972: 92), "was proposed for a definite use – namely, Christian apologetics – and not for its own sake." Augustine had made it clear in his earliest lengthy discussion of signs (389 A.D., *De Magistro*) that, in the end, signs counted for nothing apart from the interior illumination of the soul by God in the person of Christ. That this remarkable view was meant in all its force is clear from several facts. When, in 426/427 A.D., Augustine comes to reconsider his *De Magistro* (in *Retractatio* 1.12), he reaffirms its culminating teaching about Christ without even mentioning the discussion of signs that had otherwise provided the bulk of that treatise. But much earlier, in his *De Genesi adversus Manicheos* (388/389 A.D.: Sect. 2.4.5–2.5.6), he had postulated that the dependence of human communication upon signs was (in Cameron's summary, 1999: 794b), "the result of the epistemological chaos" wrought by original sin! In the *De Doctrina Christiana* itself, he lays the diversity of human languages to this same source.

Small wonder, then, that Augustine never undertook a full *ex professo* treatment of sign beyond the context of those works between 387 and 396 A.D.: *De Dialectica*, *De Genesi contra Manicheos*, *De Magistro*, *De Doctrina Christiana*.

Two weaknesses marred the proposal for a general theory as Augustine left it. The first was his failure to revisit and revise his definition of sign as requiring that it be a sense-perceptible material structure. The second was kin to this one, namely, his failure to integrate his doctrine of the interior word or concept (the *verbum quod intus lucet*) with his doctrine of the exterior or spoken word (the *verbum quod foris sonat*).

This was the "constantly alive, burning and inevitable problem" (Beuchot, 1986: 26) that Augustine bequeathed to his Latin posterity, a problem that it would take all the succeeding centuries of the Latin Age finally to resolve in the *Treatise on signs* of John Poinsot (1632). Space does not allow us to trace the lines of this solution here (but see Deely, 2001: Chaps. 6–10). Suffice to say that even Augustine's late treatment of the *verbum mentis* or 'interior word' in his *De Trinitate* (422/426) does not draw upon the perspective of sign. His radically nonsemiotic treatment of the interior word in its connection with 'exterior words' leaves his account of signs as linguistic "as running parallel to the stream of experience and alongside it, so to speak, rather than within it" (Markus, 1972: 72). Oddly, Augustine has conceived of the ultimate root of communication, the interior word, as independent of all external influence, including signs.

Yet, once psychological states along with outward signs have been brought into the perspective of the doctrine of signs, and the notion of 'doctrine' itself has been understood in its appropriate philosophical sense (Deely, 1986) respecting semiotics, it proves true that all objects depend upon the action of signs, and things are discovered within the world of objects also through the action of signs. Augustine's formula that "All doctrine concerns either things or signs, but things are learned through signs," turns out to be an anticipation of Peirce's postmodern formula that "the universe is perfused with signs, if it does not consist exclusively of them."

Austerlitz, Robert Paul (1923–1994)

A Sunshine, Columbia University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Robert Austerlitz was of the persuasion that the understanding of Language derives from the study of languages – the more distant from the observer's own, the better. Though his oeuvre overall defies labels, his devotion to Ural-Altaic, Paleosiberian, and a host of other little-studied languages formed its core. This core generated, like sparks, brilliant studies in the most diverse areas of the language sciences, including phonetics, morphology, metrics, internal reconstruction, and typology. The following draws most heavily on Abondolo, 2004, among the other sources cited.

Born in Bucharest to an Austrian father and an American mother of Bohemian ancestry, Austerlitz grew up speaking German (German, Standard), Hungarian, and Romanian. In 1938, Austerlitz came to New York where he attended Stuyvesant Public High School. Thereafter, he matriculated at New York University, but his studies were interrupted by World War II, during which he served in the U.S. Army. He resumed his undergraduate studies after the war and earned his bachelor of arts degree at the New School for Social Research in 1950. During the same year, he also earned his master of arts in linguistics from Columbia University, having written a thesis on Hungarian phonemics. Austerlitz's teachers at Columbia included André Martinet, with whom he studied Indo-European, and János Lotz, who deepened Austerlitz's interest in and exposure to Uralic languages, Hungarian philology, and metrics. His interest in Gilyak (also called Nivkh) dates to the fall of 1949, when he heard Roman Jakobson speak on 'The

nomine editum est Basileae anno 1558), the edition and text I used. Austerlitz, Robert Paul (1923–1994)

A Sunshine, Columbia University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Robert Austerlitz was of the persuasion that the understanding of Language derives from the study of languages – the more distant from the observer's own, the better. Though his oeuvre overall defies labels, his devotion to Ural-Altaic, Paleosiberian, and a host of other little-studied languages formed its core. This core generated, like sparks, brilliant studies in the most diverse areas of the language sciences, including phonetics, morphology, metrics, internal reconstruction, and typology. The following draws most heavily on Abondolo, 2004, among the other sources cited.

Born in Bucharest to an Austrian father and an American mother of Bohemian ancestry, Austerlitz grew up speaking German (German, Standard), Hungarian, and Romanian. In 1938, Austerlitz came to New York where he attended Stuyvesant Public High School. Thereafter, he matriculated at New York University, but his studies were interrupted by World War II, during which he served in the U.S. Army. He resumed his undergraduate studies after the war and earned his bachelor of arts degree at the New School for Social Research in 1950. During the same year, he also earned his master of arts in linguistics from Columbia University, having written a thesis on Hungarian phonemics. Austerlitz's teachers at Columbia included André Martinet, with whom he studied Indo-European, and János Lotz, who deepened Austerlitz's interest in and exposure to Uralic languages, Hungarian philology, and metrics. His interest in Gilyak (also called Nivkh) dates to the fall of 1949, when he heard Roman Jakobson speak on 'The

structure of Gilyak and Marr-ism' at the International Congress of Americanists at the American Museum of Natural History in New York City (Austerlitz, 1977: 16).

During the summer of 1951, Austerlitz studied Korean at the University of California at Berkeley. From the fall of 1951 through the spring of 1953, he was abroad to study Uralic (at the University of Helsinki) and Paleosiberian. The second year of these studies was supported by a Ford Foundation Fellowship. Also in 1953, he married Sylvi Nevenlinna. They subsequently had two children (Nevenlinna died in 1981). In the fall of 1953, still under this fellowship, he went to Tokyo to study Tungusic. The following spring, he undertook two months of fieldwork with a Nivkh informant (and a shaman) albeit not in her original home.

Austerlitz returned to Columbia in the fall of 1954 and completed his Ph.D. in 1955 with a dissertation on the metrical structure of Ob-Ugric folk poetry (published as Austerlitz, 1958). He began teaching in the Department of Linguistics at Columbia in 1958. In 1965, he became a full professor and from 1965 to 1968 served as department chair. He became a professor emeritus in 1993. By this point, Columbia had closed its Department of Linguistics.

The research interests Austerlitz discovered early on continued to engage him throughout his scholarly career, i.e., to the end of his life. These include: Nivkh and Ainu, and more generally Paleosiberian; Ural-Altaic languages; phonetics, phonology, morphology, historical linguistics and internal reconstruction and metrics, verbal art, and folk poetry.

Austerlitz published widely and frequently on a myriad of subjects related to his research interests (see Abondolo, 2004: 147–152 for a bibliography). He also served as an editor of *Word* from 1960 to 1965 and of publications of general linguistic interest, notably *Readings in linguistics II* (Hamp *et al.*, 1966) and *The scope of American linguistics* (Austerlitz, 1975). Over the course of his career, he was a visiting professor at many universities in the United States and abroad. Countries and institutions, no less than his colleagues, frequently recognized his distinguished scholarship and leadership with prestigious honors and appointments. In 1969, the president of Finland designated Austerlitz 'Knight First Class, Order of the Lion of Finland.' He was awarded honorary doctorates by the University of Umea in 1986 and by the University of Helsinki in 1994. In 1987 at Columbia, he delivered the University Lecture, choosing phonetics as his subject. From 1972 to 1973 he was a Senior Fellow at the National Endowment for the Humanities. He served as president of the American Oriental Society from 1981 to 1982 and as president of the Linguistic Society of America in 1990. This list is merely representative.

Austerlitz tended toward skepticism about any theory purporting to offer totalizing explanations. He preferred to anchor his thinking about linguistic phenomena in considerations of the social circumstances of individuals in a community, not because this was a better theory, but because his interest was in the realities of languages, including their social and cultural environments. This inclination seems naturally suited to, say, the study of bilingualism (Austerlitz, 1976), but it also governed his critique of long-range comparison (Austerlitz, 1991). Here he proposed that phenomena such as bilingualism may provide more natural explanations for the appearance of 'reflexes' of a lexical item across language families than does the reconstruction of 'genetic' links between the families themselves.

An article on the teaching of phonetics (Austerlitz, 1986) gave a hint of what Austerlitz's classroom was like. We see here his skepticism toward codified systems of phonetic symbols (or other terms) beyond their usefulness for the task at hand ("Insist that all symbols used in phonetics are mere ad hoc tokens and have no more than momentary validity, based on a temporary contract between the writer and the reader" (p. 1); cf. Branner, 1995), his (serious) spirit of play ("Encourage the use of self-made transcription systems . . . e.g., a flower for a voiced velar fricative" (Austerlitz, 1986: 1)), and the care with which he thought through the most effective order in which to introduce students to topics, concepts, and data. His discussion of vocalic coarticulation encapsulated several prominent features of his teaching style. "Likes," he wrote, "will exclude likes, i.e., velarized velars are less likely to occur than velarized dentals. This is a kind of incest prohibition (or: no ketchup on chicken cacciatore)" (p. 4). Here we see his knack for pithy formulation ("Likes will exclude likes"), suggestive, *echt*-structuralist analogy ("a kind of incest prohibition"), and jocular, self-reflective fillip ("no ketchup on chicken cacciatore"). The last-quoted remark may be more than a throwaway. Austerlitz was attuned to the 'grammar' of culture in all its domains, including the culinary; this is therefore arguably an instance of his penchant for serious play.

Play proved to be a subject to which Austerlitz gave some consideration toward the end of his life. His characterization of play in 'Myth, play, humor' (1988) reads as if it were his own *ars poetica*. Austerlitz defined play as experimentation with myth (i.e., accepted or sanctified norms). "Play is," he wrote, "myth-without-obligation" (p. 37). And so, in effect, was much of his own thinking (writing, teaching) about language – therein lay its power. As his succinct

essay demonstrated, far from shrinking from concepts and models, Austerlitz formulated them with virtuosity and even delight; but such things, in his eyes, were means to an end (e.g., illumination of the recesses of language), not creations worthy of canonization. Austerlitz approached his objects of study in an exploratory spirit.

Austerlitz died of cancer in September 1994. He is survived by his daughter Monica and son Paul.

Austin, John Langshaw (1911–1960)

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Austin was born on March 26, 1911 in Lancaster. After studying philosophy in Shrewsbury and Oxford, he became fellow of All Soul's College (1933) and later professor in Magdalen College at Oxford University, where he remained until his premature death on February 8, 1960. Although he was 'White's Professor of Moral Philosophy,' Austin is especially known for his contribution to linguistic philosophy and for his very personal use of ordinary language philosophy, which he applied to fundamental issues such as meaning, free will, knowledge, truth, and other minds.

Austin was averse to theory building; he was fascinated by the analytical method of lexicographers, which he used for the study of how words and phrases are used in statements about reality, in the expression of beliefs and intentions, and in all types of conventional talk. Good examples of his philosophical use of the lexicographical approach can be found in his *Philosophical papers* and in *Sense and sensibilia* (in the latter work the foundations of British logical positivism are subjected to thorough criticism).

Austin's lasting contribution to the philosophy of language and to linguistic theory (especially pragmatics) lies in having initiated what later (through the work of his student John Searle) was to become the theory of speech acts. The starting point was Austin's observation (dating back to the 1940s) that there are two essentially different types of utterances: utterances that say how things are (or say what is the matter), and utterances that, merely by being made, bring about something (a 'new reality'). Austin called the former type 'constative' utterances (*The book is on the table*), and the latter type 'performative' utterances (*I baptize you Charles*). Whereas constative utterances are (primarily) judged on their truth/falsity, performative utterances are judged on their felicity/infelicity: their (non)success depends not on what the world is like (precisely because they bring about a new fact), but on felicity conditions, such as: appropriate context, authority and sincerity of the speaker, and the existence of certain (cultural) conventions. This distinction, which is the starting point of the

essay demonstrated, far from shrinking from concepts and models, Austerlitz formulated them with virtuosity and even delight; but such things, in his eyes, were means to an end (e.g., illumination of the recesses of language), not creations worthy of canonization. Austin, John Langshaw (1911–1960)

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Austin was born on March 26, 1911 in Lancaster. After studying philosophy in Shrewsbury and Oxford, he became fellow of All Soul's College (1933) and later professor in Magdalen College at Oxford University, where he remained until his premature death on February 8, 1960. Although he was 'White's Professor of Moral Philosophy,' Austin is especially known for his contribution to linguistic philosophy and for his very personal use of ordinary language philosophy, which he applied to fundamental issues such as meaning, free will, knowledge, truth, and other minds.

Austin was averse to theory building; he was fascinated by the analytical method of lexicographers, which he used for the study of how words and phrases are used in statements about reality, in the expression of beliefs and intentions, and in all types of conventional talk. Good examples of his philosophical use of the lexicographical approach can be found in his *Philosophical papers* and in *Sense and sensibilia* (in the latter work the foundations of British logical positivism are subjected to thorough criticism).

Austin's lasting contribution to the philosophy of language and to linguistic theory (especially pragmatics) lies in having initiated what later (through the work of his student John Searle) was to become the theory of speech acts. The starting point was Austin's observation (dating back to the 1940s) that there are two essentially different types of utterances: utterances that say how things are (or say what is the matter), and utterances that, merely by being made, bring about something (a 'new reality'). Austin called the former type 'constative' utterances (*The book is on the table*), and the latter type 'performative' utterances (*I baptize you Charles*). Whereas constative utterances are (primarily) judged on their truth/falsity, performative utterances are judged on their felicity/infelicity: their (non)success depends not on what the world is like (precisely because they bring about a new fact), but on felicity conditions, such as: appropriate context, authority and sincerity of the speaker, and the existence of certain (cultural) conventions. This distinction, which is the starting point of the

William James Lectures given at Harvard University in 1955 (on 'Words and Deeds'), posthumously published as *How to Do Things with Words*, was then questioned by Austin himself, and replaced, in the course of the lectures, with a larger view on types of utterances, coupled with (semantic-pragmatic) types of verbs and with types of communicative strategies and effects. The final distinction is then one between acts (it would be better to speak of features of linguistic acts, or of power potentials or forces of acts): Austin speaks of locutionary act (act *of* saying something, with a particular sense and reference), illocutionary act (performing an act – such as warning or accusing – *in* saying something), and perlocutionary act (the act – such as frightening or offending the interlocutor – achieved *by* saying something). As different people may react differently (some are frightened when being warned, others not), the nexus between the perlocutionary force (as yielding an effect in the hearer) and the two other forces is of a non-conventional nature.

Austin did not organize these ideas into a systematic theory, nor did he live long enough to answer the objections soon made to the published version of his lectures, which shows the evolution in his approach of 'words and deeds' and ends with a number of open questions. Thus it was all the more important that Searle turned Austin's gradually revised approach into a comprehensive speech act theory.

Australia: Language Situation

P K Austin, School of Oriental and African Studies, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The languages spoken in Australia can be classified into the following:

- indigenous languages spoken by Aboriginal and Torres Strait Islander people;
- pidgins and creoles arising from language contact, primarily spoken by Aboriginal and Torres Strait Islander people and the descendants on Pacific Islander groups;
- community languages, including Australian Sign Language (Auslan) and the languages spoken by immigrant community groups and their descendants;
- Aboriginal English, primarily spoken by Aboriginal and Torres Strait Islander people;
- Australian English, the official language of the country and spoken by a first language by 90% of the population, with regional and social variation.

Aboriginal and Torres Strait Islander Languages

When Australia was colonized by Europeans in the late 18th century, it was home to approximately 250 indigenous Aboriginal and Torres Strait Islander languages (Dixon, 1980; Walsh, 1997; Angelo *et al*., 1994; Austin, 1996), many of which are now either extinct, moribund, or endangered. Today, only 12 indigenous languages continue to be learned by children (McConvell and Thieberger, 2004), meaning that 95% of Australia's indigenous heritage has disappeared or is highly threatened. Recently there have been moves toward revitalization of Aboriginal languages (see below).

The languages spoken in the Torres Strait Islands fall into two groups: Meryam Mer, spoken in the eastern islands, is related to Papuan languages to the north, and Kala Lagaw Ya, spoken in the western islands, is related to languages of the Australian mainland. For Tasmania, the existing sources are poor and

William James Lectures given at Harvard University in 1955 (on 'Words and Deeds'), posthumously published as *How to Do Things with Words*, was then questioned by Austin himself, and replaced, in the course of the lectures, with a larger view on types of utterances, coupled with (semantic-pragmatic) types of verbs and with types of communicative strategies and effects. The final distinction is then one between acts (it would be better to speak of features of linguistic acts, or of power potentials or forces of acts): Austin speaks of locutionary act (act *of* saying something, with a particular sense and reference), illocutionary act (performing an act – such as warning or accusing – *in* saying something), and perlocutionary act (the act – such as frightening or offending the interlocutor – achieved *by* saying something). As different people may react differently (some are frightened when being warned, others not), the nexus between the perlocutionary force (as yielding an effect in the hearer) and the two other forces is of a non-conventional nature.

Austin did not organize these ideas into a systematic theory, nor did he live long enough to answer the objections soon made to the published version of his lectures, which shows the evolution in his approach of 'words and deeds' and ends with a number of open questions. Thus it was all the more important that Searle turned Austin's gradually revised approach into a comprehensive speech act theory.

Introduction

The languages spoken in Australia can be classified into the following:

- indigenous languages spoken by Aboriginal and Torres Strait Islander people;
- pidgins and creoles arising from language contact, primarily spoken by Aboriginal and Torres Strait Islander people and the descendants on Pacific Islander groups;
- community languages, including Australian Sign Language (Auslan) and the languages spoken by immigrant community groups and their descendants;
- Aboriginal English, primarily spoken by Aboriginal and Torres Strait Islander people;
- Australian English, the official language of the country and spoken by a first language by 90% of the population, with regional and social variation.

Aboriginal and Torres Strait Islander Languages

When Australia was colonized by Europeans in the late 18th century, it was home to approximately 250 indigenous Aboriginal and Torres Strait Islander languages (Dixon, 1980; Walsh, 1997; Angelo *et al*., 1994; Austin, 1996), many of which are now either extinct, moribund, or endangered. Today, only 12 indigenous languages continue to be learned by children (McConvell and Thieberger, 2004), meaning that 95% of Australia's indigenous heritage has disappeared or is highly threatened. Recently there have been moves toward revitalization of Aboriginal languages (see below).

The languages spoken in the Torres Strait Islands fall into two groups: Meryam Mer, spoken in the eastern islands, is related to Papuan languages to the north, and Kala Lagaw Ya, spoken in the western islands, is related to languages of the Australian mainland. For Tasmania, the existing sources are poor and

it is difficult to say much definitively about the traditional indigenous language situation (Crowley and Dixon, 1981); however, much work has been done on reconstructing old sources (Crowley, 1993) and the Tasmanian Aboriginal Centre is promoting the revived language.

There has been growing awareness of Aboriginal and Torres Strait Islander languages among the general Australian population, and Aboriginal language courses are now taught in secondary schools in Victoria, South Australia (Nathan, 1996), and soon to be introduced in New South Wales. Bilingual education is also available in the Northern Territory, Queensland, and Western Australia, although programs are often threatened with funding cuts and lack of staff. Over the past 20 years, a number of Aboriginal-run Language Centres have been established throughout the country to collect language and culture information, prepare practical materials such as dictionaries and text collections, and to support local education and cultural revival initiatives. These grassroots organizations have been successful in mobilizing scarce resources in support of the languages. National bodies such as the Federation of Aboriginal and Torres Strait Islander Languages (FATSIL) have been set up, and Aboriginal languages have an increasing presence on the internet (see David Nathan's Aboriginal Languages Virtual Library website for sources). The Central Australian Aboriginal Media Association is also involved in broadcasting and recording and distribution of Aboriginal music. Since the 1980s, Aboriginal rock music bands, some of whom, such as Yothu Yindi, sing in indigenous languages, have become popular across Australia and internationally.

Although threatened by dominant Australian English, there are signs of indigenous language and cultural revival in South Australia (Amery, 2001) and elsewhere. In 2003, the New South Wales government committed significant funds to supporting indigenous languages in that state and introducing them into the school system in the Languages Other than English (LOTE) program.

Language Relationships

The indigenous languages spoken across the southern two-thirds of the Australian continent plus eastern Arnhemland belong to a single language family called Pama-Nyungan, originally proposed by Kenneth Hale and Geoffrey O'Grady in the 1960s. Much descriptive and comparative work, especially in the last 10 years, has provided support for this family group (see Bowern and Koch, 2003 for the most recent sources, especially the extensive cognate materials given by Alpher in that volume). In the 'Top End' (the Kimberley, Daly River, and western Arnhemland), there is much more linguistic diversity, with some 20 language families having been identified (although recent research has increasingly argued that higher level groupings may also exist; see Evans, 2003). Whether all the languages are ultimately related as a single genetic family remains to be determined.

Linguistic Characteristics

Traditionally, Aboriginal groups were multilingual, as a result of exogamous marriage patterns, and individuals spoke several languages, while claiming primary allegiance to the tongue of their descent group. Languages also showed sociolinguistic variation: geographically different dialects, and special speech styles reflecting kinship and ritual relationships (see Walsh and Yallop, 1993).

Phonologically, languages generally lack fricatives and affricates, and there are contrastive stops at up to five points of articulation, with a nasal for each stop position, one or more laterals, a flap, a semiretroflex continuant, and two glides (*see* **Gamilaraaya** and **Jiwarli** for further details). Stops and nasals contrast laminal and apical manners of articulation. There is usually no voicing contrast for stops (i.e., no contrast between *p* and *b*, for example). Most languages have just three vowels: high front *i*, high back *u*, and low *a*, with a phonemic length contrast found in about half the languages (Dixon, 1980). Some Cape York Peninsula languages have undergone historical sound changes introducing fricatives, prenasalized stops and additional vowel contrasts; Arandic languages of Central Australia are argued to have only two vowels and a contrast between rounded and unrounded consonants (see Breen in Simpson *et al.*, 2001).

The general phonotactic structure of word roots is CV(C)CV(C). Every word must begin with a single consonant and end in a vowel, or a restricted number of consonants. Some languages only allow vowel-final words (*see* **Jiwarli**). Word initially, in general only nonapical stops and nasals, and the two glides are found. Word medially, there are limited consonant clusters, primarily homorganic nasal plus stop, and apical nasal or lateral plus peripheral stop (*p* and *k*). Vowel clusters are not found, though Vowel–Glide–Vowel sequences are possible. Word stress is generally not phonemic and predictable from the phonological shape of words (*see* **Gamilaraaya** for examples).

Languages of the Pama-Nyungan (PN) group are entirely suffixing in their morphology;

non-Pama-Nyungan (non-PN) languages may show both suffixes and prefixes, and tend to be head-marking rather than dependent-marking. There are two major word classes: nominals and verbs, with nominals in PN languages typically showing rich systems of case-marking (in non-PN case-marking is often absent) and verbs marking tense/aspect/mood and dependent clause categories. Nominals can be subdivided into substantives (that cover both noun and adjective concepts in a language like English), pronouns, and demonstratives. Minor word classes include adverbs, particles, and interjections.

Nominals in PN languages typically inflect for case, with the syntactic functions of intransitive subject (S), transitive subject (A), and transitive object (P) showing a split-ergative pattern of syncretism in the case forms determined by animacy:

- for pronouns S and A fall together as a single (unmarked) form with P different (making nominative–accusative case marking);
- for other nominals, S and P fall together as a single (unmarked) form with A different, making ergative–absolutive case marking.

In some languages, some nominal categories (e.g., animate nouns) show a three-way contrast distinguishing S-A-P. In non-PN languages, there are typically systems of verb affixation encoding agreement with verb arguments; this agreement may also reflect gender categories of the nominals.

The following cases are also typically found in PN languages:

- dative, marking alienable possession and direction toward a place;
- locative, coding location in a place;
- ablative, coding direction from a place, and cause.

Australian languages typically have complex systems of nominal word-building morphology that involves suffixation between the root and case inflection. Categories encoded in word-building morphology include number, having, and lacking. Some non-PN languages encode gender on nouns via affixation.

Pronouns generally distinguish three persons and singular, dual, and plural number; in the first person nonsingular, there is an inclusive–exclusive contrast in about half the languages. Some languages also show bound pronouns, often these are reduced forms of the free pronouns and in PN languages are suffixed to particular elements of the clause (Dixon, 1980).

Verbs morphologically distinguish between main verb and dependent verb inflections. Main verbs encode tense and mood categories, while dependent verbs occur in hypotactically linked clauses and mark relative tense (and is some central Australian languages also switch-reference; see below). There are typically a number of verb conjugations that are morphologically determined but may show some correlations with transitivity (Dixon, 1980). Verbs show productive word-building morphology, including affixes that indicate aspectual categories or change in transitivity (detransitivizing and transitivizing processes). Generally passive forms are not found, though some eastern Australian languages have antipassive derivations. Non-PN languages show agreement via affixation on the verb. The minor categories of adverb, particle, and interjection show no morphological variation. All languages also have affixes that attach to words of any category, typically encoding discourse status, evidentiality, and other pragmatically based meanings.

A common pattern in many Australian languages (*see* **Jiwarli**) is for word order to be relatively free and hence to find all possible orders of Subject, Object, and Verb, as well as separation of nouns and adjectives referring to a single entity (with case agreement indicating common reference). Similarly, possessors (in dative case) may precede or follow the alienable possessed noun. Free omission of nominals whose reference is clear from the context is also common. Australian languages have become famous for their 'nonconfigurational syntax.'

Interclausal syntax shows a degree of variation; some languages (*see* **Gamilaraaya**) place little restriction on linking of clauses, while others such as Dyirbal have 'ergative syntax' where the linked clauses must share coreferential absolutive (S or P) nominals. Many central Australian languages have switch-reference where cross-clausal identity or nonidentity of subjects (S or A) is encoded on the dependent verb. Non-PN languages tend to make use of parataxis in clause linkage.

Particles in Australian languages tend to have scope over the whole clause and encode such semantic concepts as polarity (affirmation versus negation) and mood (possibility, negative imperative, etc.).

Pidgins and Creoles

Australia has a number of English-based pidgins and creoles as a result of language contact between the indigenous languages and the English of the colonizers, beginning in the late 18th century. A range of geographically diverse forms have been and are found, including Sydney-pidgin (extinct since the 19th century; Troy, 1990), Kriol of the 'Top End,' Cape York Creole (Crowley and Rigsby, 1979), and Broken or Blaikman Tok of the Torres Strait islands (see Schnukal in Angelo *et al.*, 1994). Kriol is now the

native language of some 30 000 speakers in northern Australia.

The various creoles show clear influence from Australian indigenous languages both lexically and structurally (e.g., distinguishing singular, dual, and plural pronouns, and inclusive–exclusive reference in the nonsingular). They also share many characteristics with Pacific pidgins and creoles such as Tok Pisin and Bislama.

The descendants of Pacific islanders removed to Australia in the 19th century to work on sugar plantations in Queensland spoke Pacific pidgins and creoles – these are now being replaced by Aboriginal English.

Community Languages

As a result of on-going immigration of non-English speakers into Australia, some 200 languages have been added to the linguistic ecology of the country (see Clyne, 1991; Clyne and Kipp, 1997). The distribution of these 'community languages' varies regionally, especially between the major urban centers, e.g., Melbourne adolescents show dominance of Italian and Greek (reflecting immigration after the Second World War), while Sydney shows dominance of Arabic and Chinese languages (reflecting more recent immigration from the middle East and Southeast Asia). All community languages are undergoing shift to English (Clyne and Kipp, 1997), though to varying degrees in different communities (e.g., more highly among Dutch than Poles or Maltese and Turks). Community languages are widely taught in schools (as LOTE), and bilingual education (including immersion programs) is available in some languages. Local governments in Australia, particularly in the urban centers, pay attention to community languages and provide services and information in a range of languages. There is a system of registration for interpreters and translators, and strong infrastructure of telephone and court interpreting services for non-English speakers.

An important community language is Australian Sign Language (Auslan), which is widely used in the deaf community, and differs in significant ways from American Sign Language (ASL) and British Sign Language (BSL). After being ignored for a long time, research and publications on Auslan have appeared over the past 15 years (see Johnston, 1989, for example) and an active program of documenting Auslan is underway. Because of early diagnosis of deafness and the widespread use of cochlear implants in deaf children, the number of native Auslan signers has shown a dramatic decline in recent years; the language is currently endangered.

Aboriginal English

Aboriginal English is a particular form of Australian English primarily spoken by Aboriginal and Torres Strait Islander people. It is spoken as a first or second language and is a continuum that ranges from varieties that resemble pidgin or creole English to those more like nonstandard Australian English (Eagleson, 1983; Eades, 1991; Kaldor and Malcolm, 1991). Aboriginal English in rural settings shows substrate influence in articulation (having apico-domal (retroflex articulations) and replacement of fricatives with stops, for example), lack of copula, lack of number marking and *bin* as a past tense marker. In urban settings, Aboriginal English shows many features found in nonstandard varieties across the world, such as multiple negation, and nonstandard verb agreement; however, there are lexical and pragmatic features (Eades, 1991) that are distinctive. Even in regions such as Sydney and Melbourne where the indigenous languages ceased to be spoken in the 19th century, Aboriginal English contains lexical items derived from the indigenous languages such as *koorie* 'Aboriginal person' and *goom* 'alcohol.'

Australian English

A distinctive Australian variety of English (AustEng) is spoken by 90% of the 20million inhabitants of the continent, with regional and social variation. AustEng has its origins in the English dialects brought by mainly English and Irish settlers in the 18th and 19th centuries, to which have been added the speech of immigrants from all over the world. Long regarded as a substandard form of speech and lacking prestige (Turner, 1994), AustEng has become accepted over the past 20 years and has been codified in dictionaries (including the Macquarie Dictionary in various versions dating from 1981, also now with a strong web presence, and the Australian National Dictionary), is used in English language teaching in Australia, and has been popularized in textbooks (e.g., Burridge and Mulder, 1998). It is now the prestige variety of English-language broadcasting. Like most other varieties of English, AustEng is currently being subjected to influence from American English, especially in the lexicon, but also in pronunciation (Burridge and Mulder, 1998).

Australian English shows a large number of loan words from indigenous languages (the Australian National Dictionary records over 400), especially for the distinctive flora and fauna of the country, and for place names, e.g., *kangaroo*, *billabong*, *waratah*, and *galah*, or *Woomooloo* and *Mordialloc* (see Dixon *et al.*, 1990 for other examples). Other sources

Table 1 Australian English vowels

Broad	*General*	*Cultivated*	*Key word*	*RP*
	ɪ		*kit*	ɪ
	e		*dress*	e
	æ		*trap*	æ

	ʊə - ɔː - ʊːə - ʊː		*cure*	ʊə

of distinctive lexical materials include English dialects, convict slang, and rhyming slang, e.g., *Joe Blake* for *snake*, as well as locally developed terms, e.g., *outback*.

AustEng shows a degree of regional variation, particularly in vocabulary and pronunciation. Lexical variation has been well researched and increasingly documented in the dictionaries, while variation in pronunciation has been less studied. Among features that show geographical differences are [æ] vs. [a] in *graph* or *dance*, postvocalic vocalization of *l* (in words like *eagle*), lowering of low front [ɛ] (in words like *Mel*, *helicopter*) and bisyllabification of past participles (so that *grown* sounds like *grow-en*).

Social variation in Australian English has been well studied since Mitchell and Delbridge (1965) established the categories of Broad, General, and Cultivated Australian. The differences are particularly clear phonetically in vowel nuclei, especially the diphthongs of *face*, *price*, *goat*, and *mouth* (see Harrington *et al.*, 1997). Table 1 below (from Melchers and Shaw, 2003: 105, based on Wells, 1982) shows the variants of Australian English vowels in comparison to Received Pronunciation.

Melchers and Shaw (2003: 104) list the following as especially salient features of AustEng:

- front [aː] in *palm*, and *start* (shared with New Zealand English)
- wide diphthongs in *fleece*, *face*, *price*, *goose*, *goat*, and *mouth*;
- close front vowels, in *dress*;
- extremely productive use of two noun suffixes *-ie* and *-o*,
- use of *she* as a generic pronoun, e.g., *she'll be right* 'it's fine';
- highly characteristic vocabulary, some drawn from indigenous languages, some from British dialect slang, and other elements locally developed.

Note also that AustEng differs from RP in having schwa in unstressed syllables, intervocalic voicing and flapping of *t*, and shares with it lack of postvocalic *r* found in American and Canadian English. A distinctive high rising terminal intonation contour, noticed by Mitchell and Delbridge (1965) and investigated in depth for Sydney speech by Horvath (1985), is characteristic of female, teenage, and lower working class speech.

Morphologically, AustEng is characterized by a high degree of clipping, e.g., *uni* for *university*, *Oz* for *Australia*, which may or may not be combined with highly productive suffixation of *-ie* or *-o*, as in *Salvos* for *Salvation Army*, *maggie* for 'magpie,' *sunnies* for *sun glasses* and *lippie* for *lipstick*.

Introduction

Archeological evidence indicates that Australia has been inhabited by humans for over 50 000 years. At the time of the establishment of the first British colony at Port Jackson (Sydney), in 1788, there were about 250 different languages spoken on the continent. Estimates of the Aboriginal population at that time vary from the low figure of 300 000 to several times that number. Over a period of a little more than 100 years, Europeans took over the whole country, killing a large proportion of the indigenous population in the process. Today only 60 or so Aboriginal languages are still spoken, and as few as 20 or so are likely to be spoken a generation from now.

For almost all the native languages, we have some record, though in some cases only a brief English–Aboriginal word list. Grammatical information is available for approximately 100 languages, the bulk of it having been collected since the 1960s, in many cases from the last speakers.

Classification

Capell classified Australian languages typologically into two groups: suffixing and prefixing, the latter group being confined to an almost continuous area in

Australian Languages

B J Blake, La Trobe University, Bundoora, Victoria, Australia

Introduction

Archeological evidence indicates that Australia has been inhabited by humans for over 50 000 years. At the time of the establishment of the first British colony at Port Jackson (Sydney), in 1788, there were about 250 different languages spoken on the continent. Estimates of the Aboriginal population at that time vary from the low figure of 300 000 to several times that number. Over a period of a little more than 100 years, Europeans took over the whole country, killing a large proportion of the indigenous population in the process. Today only 60 or so Aboriginal languages are still spoken, and as few as 20 or so are likely to be spoken a generation from now.

For almost all the native languages, we have some record, though in some cases only a brief English–Aboriginal word list. Grammatical information is available for approximately 100 languages, the bulk of it having been collected since the 1960s, in many cases from the last speakers.

Classification

Capell classified Australian languages typologically into two groups: suffixing and prefixing, the latter group being confined to an almost continuous area in

Figure 1 Pama-Nyungan and northern Australian languages.

the north of the continent (see Figure 1). In the suffixing group, all affixes are suffixes, while in the prefixing group there are some prefixes, mainly pronominal forms for subject and object (Capell, 1956: 31–60). The suffixing languages are predominantly agglutinative, but in the prefixing languages there is more fusion, mainly in the pronominal and other prefixes to the verb.

The languages of the mainland are generally thought to be related, since certain roots are widespread. These include lexical roots, such *na* 'to see,' *mil* 'eye,' and *yan* 'to go,' and grammatical roots, such as *nga-* 'first person,' *nu* 'he,' and *ku* 'dative case marker'. In 1966 O'Grady, Wurm, and Hale produced a classification that recognized 29 'families' (O'Grady *et al.*, 1966a; O'Grady *et al.*, 1966b), but more recent work by various scholars has demonstrated that the figure could be reduced to as few as a dozen or so. The basis of the classification was lexicostatistical, and 'family' in this context meant a group of languages that could be linked on the basis of any member's sharing 15 percent or more of basic vocabulary with any other member.

A notable feature of the O'Grady *et al.* (1996a,b) classification is that one family, the Pama-Nyungan family, covers most of the mainland except for the Kimberleys and the Top End. It coincides roughly with the suffixing languages, taking in the Yolngu languages of northeast Arnhem Land, which represent an enclave of suffixing among the prefixing languages. The name Pama-Nyungan is derived from *pama* 'man' in the northeast of the continent and *nyunga* 'man' in the southwest.

Blake showed that between Pama-Nyungan and the other (Northern) languages, there are some consistent differences in the forms of some pronouns. For instance, while most Pama-Nyungan languages have a first person dual pronoun *ngali*, this is absent from the Northern languages, and while most Pama-Nyungan languages reflect a second singular **ngin*, a

majority of Northern languages reflect *$ngin^y$ with a palatal nasal as the third segment. A number of Pama-Nyungan languages have a third person pronoun root *nhu-*, whereas the Northern languages have *nu-*(Blake, 1988: 13). Blake's classification involved some reclassification, taking the Tangkic languages of the Gulf of Carpentaria to be Northern, and Yanyuwa to be Pama-Nyungan. Garrwa (Garawa) and Waanyi (Wan[j]i) are two languages with some Northern and some Pama-Nyungan pronouns.

Evans demonstrated that there is a regular correspondence between Pama-Nyungan and the Northern languages, reflecting a phonological change in Pama-Nyungan in which initial apicals (*t*, *n*, *l*) merged with laminals (dental or palatal), the *nhu-/nu-* correspondence in the third person singular pronoun being part of the evidence for this change (Evans, 1988: 98–100).

While Blake and Evans provided evidence for a revised Pama-Nyungan that went beyond the lexicostatistical, in his recent book of Australian languages, Dixon argued strongly against the existence of Pama-Nyungan. He argued that the pronouns that characterize so-called Pama-Nyungan such as *ngali* 'we two' have diffused. He showed that the original lexicostatistical classification was flawed and that the shift in initial apicals to laminal did not coincide exactly with Pama-Nyungan. He also pointed out that no fauna or flora terms had been reconstructed that could be attributed to Proto-Pama-Nyungan (Dixon, 2002). Nevertheless, Australianists have so far not been convinced by Dixon's arguments (see, for instance, the papers in Bowern and Koch, 2004).

As noted in this article, the languages of the mainland look as if they are related, though Dixon was pessimistic about the prospects of demonstrating this by the comparative method. There are several factors militating against reconstructing anything like Proto-Australian: the enormous time depth, demonstrable diffusion, and paucity of data, particularly for the southeast, which was taken over by Europeans early and was heavily settled.

It has not been possible to relate the languages of Tasmania to those of the mainland. Tasmania was cut off from the mainland about 14 000 years ago, when the earth warmed as it slowly emerged from the last Ice Age and the sea level rose, resulting in an unnavigable strait (Bass Strait) between Tasmania and the mainland. Given a time depth of 14 000 years for the period of separation, it is likely that any evidence of a genetic connection would have been obliterated.

It has likewise not been possible to establish a genetic connection between any Australian language, whether from the mainland or Tasmania, and any language from elsewhere.

Phonology

In Europe the phonologies of English, French, German, Italian, and Polish are quite different, but the mainland languages of Australia tend to be similar in their inventory of phonemes and in their phonotactics (word shapes). All Australian languages have stop sounds, but there is typically only one set, represented either by *p*, *t*, *k*, etc., or by *b*, *d*, *g*, etc. Normally five or six stops are found: labial (*p*), apico-alveolar (*t*), apico-postalveolar or retroflex (represented here by *rt*), dorso-velar (*k*), and one or two laminal stops. Where there is one laminal stop, the pronunciation may range from dental to palatal, and by convention this stop is represented as palatal (*tj*). Where the dental and palatal stops are phonemically distinct, the dental is usually represented as *th*. Corresponding to each stop is a nasal. There is always one lateral (*l*), but there may also be dental (*lh*), palatal (*ly*), or retroflex (*rl*) laterals. Commonly there are two rhotics: a glide often described as retroflex and a flap, or trill. These are represented here by *r* and *rr,* respectively. All Australian languages have a labio-velar glide (*w*) and a palatal glide (*y*). Figure 2 displays the consonants commonly found in Australian languages.

The majority of Australian languages have only three vowels (*i*, *a*, and *u*), though often there are long and short versions, which gives effectively six vowels. Some languages have *e* or *o* or both.

Words in Australian languages usually have more than one syllable, and more often than not they end in a vowel.

Although Australian languages right across the continent tend to have quite similar phonological systems, a few languages in a number of quite separate areas have undergone a series of phonological changes involving the loss of initial consonants or even whole syllables. In a number of Pama-Nyungan languages, there is a word *kumpu* for 'urine.' In Nhanda (western Australia), the initial consonant has been lost to yield *umpu*; in some languages of Cape York, the first syllable has been lost to give *mpu*; and in the Arandic languages of central Australia, the form *mpwa* occurs, the *k* having been lost and the *u* being reflected as labialization of the *mp* cluster. The effect of these changes has been to make some languages look quite atypical, and at one stage certain languages, such as Nganyaywana, were thought to be unrelated to other mainland languages, because cognate forms could not be readily recognized.

Figure 2 Consonants.

Morphology and Syntax

Inflection apart, words may be simple, compound, or reduplicated. In Pitta Pitta, for instance, *ngampa-manha* (stomach-bad) is 'sad,' and reduplicated forms of *ngapu* 'water,' *mayi* 'dirt,' and *maka* 'fire' yield *ngapu-ngapu* 'wet,' *mayi-mayi* 'dirty' and *maka-maka* 'hot.' The most common means of deriving new words is via suffixes. An almost ubiquitous feature of Australian languages is the presence of a suffix for 'having' and a suffix for 'lacking,' though the actual forms employed vary a good deal from language to language (see [1] and [3] for examples). In Pitta Pitta, for instance, we find forms like *kanga-maru* (alcohol-having) 'intoxicated' and *nhupu-yaku* (spouse-lacking) 'unmarried.' Most languages have suffixes to mark the derivation of nouns from verbs and vice versa. In Diyari *wirlpa-nganka* 'to make a hole' is formed from the noun *wirlpa* 'hole,' and from this stem can be derived the noun *wirlpa-mganka-ni* 'opener.' Most languages have a suffix to mark the derivation of intransitive verbs from nouns, often with an inchoative sense. In Dieri we find formations such as *kilpa-rri* 'become cool' and *yapa-rri* 'become afraid.' Causatives of intransitive verbs are also common as in Diyari *pali-ma* 'to extinguish a fire,' from *pali* 'to die.' The majority of Australian languages express reflexive and reciprocal notions by using a derived intransitive verb. In Diyari we find *muduwa* 'to scratch' (transitive) and *muduwa-thadi* 'to scratch oneself.' Note the *d* in these words. Diyari has a voicing contrast in apical stops.

In the Pama-Nyungan languages, all derivational and inflectional affixes are suffixes. Nouns are marked for case, and verbs are marked for categories such as aspect, tense, and mood. In some languages, case concord extends from the head noun to its dependents; in others, it occurs only on the final word in the noun phrase.

With only a handful of exceptions, nouns in Pama-Nyungan languages take ergative case marking when functioning as the agent of a transitive verb (A) and zero case marking when functioning as the sole argument of an intransitive predicate (S) and a direct object (O). The following examples are from Margany, a language of southwestern Queensland.

(1) Nguda barndin-bayi.
dog dirt-having
'The dog is dirty.'

(2) Nguda-nggu yurdi gamba-nhi.
*dog-*ERG *meat bury-*PRES
'The dog is burying the meat.'

On the other hand, in most Pama-Nyungan languages pronouns serving as S or A are treated alike (normally the bare stem is used, at least with nonsingular pronouns), while a pronoun in O function takes accusative case marking. This, too, can be illustrated from Margany.

(3) Ngali bulu-idba.
*we.two food-*LACKING
'We have no food.'

Table 1 Margany case marking

English	stone	we two
nominative	*barri*	*ngali*
ergative	*barringgu*	*ngali*
accusative	*barri*	*ngalinganha*
genitive	*barrigu*	*ngalingu*
dative	*barrigu*	*ngalingun.gu*
allative	*barridhadi*	*ngalingundhadi*
locative	*barringga*	*ngalingunda*
ablative	*barrimundu*	*ngalingunmundu*
instrumental	*barringgu*	*ngalingundu*

(4) Gara ngali nhaa-nhi ina-nha.
not *we.two* *see*-PRES *you*-ACC
'We can't see you.'

Typically there is a dative case, an allative ('to'), a locative ('at'), an ablative ('from'), frequently a genitive, and sometimes a causal or aversive that can cover cause, as in 'I'm sick from (eating) bad meat,' or what is to be avoided, as in 'Keep away from the fire.' The paradigms of Margany case forms displayed in Table 1 are typical with respect to both forms and categories. However, there is one idiosyncratic difference. The ergative case marker covers not only instrumental function, as it does in the majority of Pama-Nyungan languages, but also the causal or aversive sense alluded to in this article. In this function it can occur with pronouns and contrasts with the unmarked form used for the agent of a transitive verb.

A feature of case marking in Australian languages is the prevalence of double case marking. This is found, for instance, where a genitive-marked dependent of a noun displays case concord with its head, as in Margany.

(5) Ngaya waban-gu ngali-ngu-ngga bama-ngga.
I *go*-PURP *we*-GEN-LOC *bro*-LOC
'I'm going with our brother.'

In about two-thirds of Australian languages, there are bound pronominal representations, either clitic pronouns or inflection, for subject (S and A) and object (O), and in a few languages there are forms for other complements or adjuncts, such as recipients or beneficiaries. In the suffixing languages, these pronominal elements are suffixed to the verb or to the first constituent in the clause.

Examples (6), (7), and (8), from Pitjantjatjara, illustrate the contrast between *-rna* the S/A(subject) form and *-rni* the O form. In this language, the bound pronouns are enclitic to the first constituent in the clause.

(6) Munu-rna purta kapi-ku kutju a-nkuku?
and-I.SUBJ QUERY *water*-DAT *alone* *go*-FU
'And should I go for water alone?'

(7) Purnu-rna mantji-nu.
wood-I.SUBJ *get*-PT
'I got the wood.'

Example (8) illustrates the double object construction, with a verb for 'give' in which the noun serving as patient object is unmarked, while the recipient is represented by both an accusative marked pronoun and a bound object pronoun that is enclitic to the first constituent. There is no overt form for third person subject.

(8) Minyma-ngku-rni mayi ngayu-nya u-ngu.
woman-ERG-*1*SG.O *bread* *1*SG-ACC *give*-PT
'The woman gave me bread.'

In some languages, there is a detransitivized construction in which the agent of a two-place verb is encoded as S and the patient is expressed in the dative or some other oblique case. The following pair of sentences from Pitta Pitta (Queensland) illustrate the normal transitive construction and the derived intransitive construction, which, following Silverstein (1976), is generally known as the antipassive (AP). Pitta Pitta and some other related languages of western Queensland are unusual in that they have both ergative and accusative marking on all nouns and pronouns.

(9) Pithi-ka nga-thu ina.
hit-PT *I*-ERG *you*.ACC
'I hit you.'

(10) Pithi-li-ya ngantja in-ku.
hit-AP-PRES *I* *you*-DAT
'I feel like hitting you.'

The antipassive has a different semantic function in different languages, but it always signals some kind of reduced semantic transitivity. In Pitta Pitta, it signals desiderative aspect.

Pitta Pitta uses a construction similar to the antipassive in the future tense. The verb is unmarked, there being neither the derivational antipassive nor the past or present inflection, and the subject (S or A) bears a special future subject inflection.

(11) Pithi nganyu in-ku.
hit.FU *I*.FU.SUBJ *you*-DAT
'I'll hit you.'

Pama-Nyungan languages are generally referred to as 'ergative'; this term indicates that they exhibit ergative case marking on the agent of a transitive verb. While most of these languages are like Margany, in that the ergative marking is found only on nouns and is complemented by accusative marking on pronouns, a handful of Pama-Nyungan languages – including Warlpiri, Kalkutungu (Kalkutung), and Yalarnnga – have ergative marking on both nouns and pronouns in A function, but no accusative marking

on any free nominals. About two-thirds or more of Australian languages have bound pronominal representation for core functions, and these bound pronouns, with only a very few partial exceptions, operate on the basis of a subject (S and A) form and an object form (O).

Dixon (1972) argued that in Dyirbal, syntactic rules are sensitive to the grouping S + O, as opposed to A. This phenomenon has come to be referred to as ergative syntax, as opposed to accusative syntax; the latter term refers to a system of syntactic rules based on the notion of S + A (i.e., subject), as in English and numerous other languages. Ergative syntax is also found in some of Dyirbal's neighbors, including Yidiny, and in two adjacent languages of western Queensland, Kalkutungu (Kalkutung) and Yalarnnga. It manifests itself in a number of rules. For instance, there is a requirement that in relative clauses, the relativized function, which is covert, can be only S or O. To relativize an agent, the relative clause must be detransitivized via the antipassive, which thereby converts a potential A into S. In purpose clauses (also used for indirect commands), antipassive is used to signal that A is coreferent with S or O. The examples in (12) and (13) are from Yalarnnga. In the nature of things, coreference between S and A is common (as in [12]) and between P and A (as in [13]). In both these patterns of coreference, the antipassive is used.

(12) Ngani-mi ngiya manhi-wu miya-li-ntjata.
go-FU *I* *food*-DAT *get*-AP-PURP
'I'll go and get food.'

(13) Tjuwa tjala ngathu ngapa-mu,
boy *this* *I*.ERG *tell*-PT
watjani-wu pinpa-li-ntjata.
wood-DAT *gather*-AP-PURP
'I told this boy to gather firewood.'

The example in (14) provides a nice contrast. Here there is coreference between S in the second clause and P in the third, and there is no antipassive.

(14) Ngathu tjala ngapa-mu ngani-ntjata
I.ERG *this* *tell*-PT *go*-PURP
marnu-yantja-mpa karri-ntjata.
mother-HIS-ALL *wash*-PURP
'I told him to go to his mother and get washed.'

In (15) there is coreference between A and A, and no antipassive.

(15) Ngathu miya-ntjata yimarta
I.ERG *get*-PURP *fish*
yunkunhi-nti-yarta yita-wampa.
return-CAUS-PURP *this*-ALL
'I am going to get some fish and bring it back here.'

It appears, however, that ergative syntax is not common in Australia, despite the widespread use of ergative case marking. In a number of languages with ergative case, there are syntactic rules based on the familiar grammatical relation of subject (S + A). Many such rules have to do with showing maintenance of reference or switch reference. In Pitjantjatjara, for instance, the conjunction *munu* is used to link clauses with the same subject (SS), while *ka* is used to link clauses where there is a change of subject (DS). The point is that the rules operate on the basis of S and A, not S and O, as in languages like Dyirbal.

(16) Tjitji panya ngarrikati-ngu munu
child *that* *lie*-PT *and*.SS
ngarri-ngi kunkunpa ka kurta
lie-PT-IMPF *sleep* *and*.DS *old.bro*
panya paka-rnu.
that *get.up*-PT
'The child lay down and was lying asleep and the older brother got up.'

In a small group of Pama-Nyungan languages in western Australia, there is no ergative marking at all. The subject (S + A) appears in the nominative case, and the object (O) in the accusative/dative case. This group includes Ngarluma, Panyjima (Panytyima), and Yindjibarndi. It has been argued that these accusative languages derive from ergative languages via the generalizing of detransitivized constructions of the type illustrated in (10) and (11).

The non-Pama-Nyungan or Northern languages span the Northern part of the continent from western Australia to the Gulf of Carpentaria. With a few exceptions, mostly at the eastern end of their range, the Northern languages have bound pronominal elements for subject and object prefixed to the verb. In some languages, these pronominal elements are separable, but more often than not, they fuse to one another and to other formatives in the verb. There is no accusative case marking on nouns or free pronouns, though there is ergative marking in some languages.

Among the prefixing languages, but also in the northwestern suffixing languages, it is common to find that only certain verbs can bear inflection. These verbs can appear on their own, as in (17), or they can act as auxiliaries in concert with an uninflected lexical verb, as in (18). These examples are from Maranungku (Maranunggu).

(17) Tawun kangani yi.
town NONFU.*I.go* PT
'I went to town.'

(18) Tirr wuttar wat kangani yi.
edge sea walk NONFU.*I.go* PT
'I walked to the beach.'

Systems of noun classes are common among the Northern languages, though a rarity in the Pama-Nyungan family. A majority of the Northern languages of the Kimberleys and the Top End have from two to eight noun classes, with each class marked by a prefix. The classification typically includes a masculine class, a feminine class, and a class for vegetable food. It is thought that these class markers are derived generic nouns. It is not uncommon in Australian languages to use a generic noun accompanied by a specific noun. See, for instance, (26). The vegetable class marker is *m-*, *ma-* or *mi-*, and *mayi* is a widespread word for 'vegetable food,' so it is thought likely that the former derives from the latter. These class markers may appear not only on nouns representing direct dependents of the verb but also on associated demonstratives and appositional nouns. They may also appear on the verb, where they serve as crossreferencing pronominal forms. In the following example from Ngandi, *ni* (masculine) and *gu* (marking one of the inanimate classes) appear prefixed to the subject and object nouns respectively, and they are also prefixed to the verb.

(19) Ni-gu-may ni-yul-thu gu-dyundu.
NI-GU-*got* NI-*man*-ERG GU-*stone*
'The man got the stone.'

The noun phrases in (19) can be omitted. *Ni-gu-may* can stand as a sentence on its own, meaning 'He got it' or, more precisely, 'A member of the *ni* class got a member of the *gu* class'.

A feature of the prefixed bound pronoun systems is the prevalence of hierarchical principles of ordering or marking. In Gunwinygu (Gunwinggu) (Northern Territory), first and second person forms always precede third, irrespective of which is subject.

(20) Nga-n-di bun.
1SG-OBJ-3PL *hit*
'They hit me.'

(21) Nga-be-n bun.
1SG-3PL-OBJ *hit*
'I hit them.'

The form *n-* glossed as object is common among the prefixing languages. In some languages this behaves like an inverse marker, in that it is used only when a person lower on the hierarchy acts on a higher person. This is the situation in Rembarnga (Rembarunga), where the hierarchy is 1 > 2 > 3PL > 3SG. Note that it does not appear in (22), where first acts on third, but it does appear in (23), where third plural acts on first.

(22) Pa-nga-na.
3PL-1SG-*saw*
'I saw them.'

(23) Nga-n-pa-na.
1SG-O-3PL-*saw*
'They saw me.'

A number of Northern languages incorporate nominals into the verb. The incorporated forms are often different from the corresponding words used outside the verb, and the range of concepts that can be incorporated is usually relatively small. The following example is from Tiwi, in which the incorporated form *wuliyondyi* refers to the direct object represented by *ti*.

(24) Pi-ti-wuliyondji-rrurlimpirr-ani.
3PL-3SG.FEM-*dead.wallaby-carry.on.shoulders-*
PT.HABIT
'They would carry the wallaby on their shoulders.'

Incorporated forms tend to correspond to the object of the verb, but they can correspond to other complements or adjuncts or to the subject of an intransitive verb.

Example (24) is fairly typical of Tiwi and of a number of other Northern languages that can be described as polysynthetic incorporating languages. Tiwi is obviously of quite a different type from Margany, which has no bound pronouns, or even Pitjantjatjara, which does. Tiwi has no case marking at all, and relations of complements and adjuncts to the verb are signaled via three series of bound pronouns representing subject, direct object, and indirect object, plus a few local prepositions. Not only are relations within the clause marked on the verb, but the possessive relation is signaled within phrases by cross-referencing the possessor on the possessed (head) noun. 'Purrukuparli's son' is expressed as *Purrukuparli ngarra-mirani*, literally 'Purrukuparli, his son.'

Most Australian languages appear to have very free word order. Not only can the predicate, its complements, and its adjuncts appear in any order, but even the sets of words that translate a noun phrase of English may be separated. A common pattern is for a more general term, such as a pronoun or a generic noun, to be placed first, with the modifier late, often at the end. The example in (25) is from Nyangumarda (Nyangumarta).

(25) Nyungu ngawu tjininganinyi
this mad make.1PL.O
walypila-mila-lu kari-lu.
white.man-GEN-ERG beer-ERG
'This is making us silly, the white man's beer.'

The strategy employed in (25) is common in Australian languages. Another variation on this tendency is to use a generic noun early in the sentence and then a specific noun later, as in (26), from Yidiny.

(26) Ngayu minya bugang ganguul.
I animal eat wallaby
'I'm eating wallaby.'

The fact is that most Australian languages have pragmatic principles rather than grammatical rules for word order. One such principle that is widespread is to put the focus (the emphasized phrase) first. There is probably no Australian language with word order as rigid as in English, but some languages have very strongly preferred orders. Some languages in the interior of the continent, including Pitjantjatjara, have fairly regular subject-object-verb order, and a few, such as Garrwa (Garawa), are predicate-initial.

Semantics

The Australian Aborigines were hunter-gatherers, and naturally the vocabularies of Australian languages are rich in terms for fauna and flora as well as in terms for hunting and catching animals. There is regularly a distinction, for instance, between hitting or killing with a missile and hitting or killing with the hand or a handheld implement. There are words for decoy devices for attracting birds, words for a noose on a stick to catch a bird, words for different kinds of spears and boomerangs, and so on. Some semantic distinctions that are quite different from any made in European languages intrude into the grammar. In some Northern languages, there are forms for 'you and I' that pattern as singulars, i.e., the speaker and addressee are treated as a unit. This becomes obvious when we examine the distribution of dual and plural marking. In Table 2 the prefixed pronominal forms in Gunwinygu (Gunwinggu) are presented. The form *ngarr-* for 'thou and I' does not take dual marking but contrasts with a dual-marked form *ka-ne*, meaning 'speaker and two addressees,' and a plural-marked form *ka-rri*, meaning 'speaker and three or more addressees.'

Table 2 Gunwinygu (Gunwinggu) pronominal prefixes

Number	*Singular*	*Dual*	*Plural*
1	*nga-*	*ngane-*	*ngarri-*
12	*ngarr-*	*kane-*	*karri-*
2	*yi-*	*ngune-*	*ngurri-*
3	Ø	*bene-*	*birri-*

In some languages there are different nonsingular pronouns for the kinship relations between the people referred to. In Alyawarra (Alyawarr), for instance, *mpula* means 'you two' but is used only for two people who belong to the same section. Among the Alyawarra everyone belongs to a patrimoiety, and within each patrimoiety there are two sections of alternating generations. There is a separate pronoun, *mpulaka*, for two people who are members of the same patrimoiety but not the same section (e.g., father and child), and a third form, *mpulantha*, for two people belonging to different patrimoieties (e.g., mother and child). This system of distinctions applies to all dual and plural pronouns.

Avoidance and Secret Vocabularies

In Aboriginal society it is common to have a special vocabulary that is to be used in the presence of certain kin. Normally a man is required to avoid dealings with his mother-in-law, for instance, and the prohibition covers real, prospective, and classificatory mothers-in-law. In some areas a man is required to use the special vocabulary in the presence of a mother-in-law, and such special vocabularies have come to be called 'mother-in-law languages,' though they are not separate languages, nor are they always reserved for speech in the presence of a mother-in-law.

Secret languages have also been reported from a number of areas. Like forms of avoidance language, these are special vocabularies usually taught as part of male initiation.

All these special vocabularies are of great linguistic interest. They typically consist of only a few hundred words, and often one finds a generic term in the reduced vocabulary that is lacking in the everyday language. In the avoidance language of the Dyirbal (Queensland), for instance, there is a single word, *dyidyan*, for any lizard, skink, or goanna, and a single word, *dyiburray*, for any possum, squirrel, or glider. However, in the everyday language, there are words only for particular species (Dixon, 1980: 61).

Sign Language

Over much of central and northern Australia, sign language is used as an alternative to speech. Signs are made with the hands and correspond to words in the spoken language and to particles and suffixes that have local meanings, such as 'to' or 'here.' Sign language is traditionally used in a variety of contexts,

including rituals, during periods of mourning when speech is proscribed, in conversing over long distances, or in hunting, where silence is important.

The Future of Australian Languages

Only a score or so of Australia's native languages are being passed on to the next generation. Over the past three decades, there have been bilingual programs aimed at helping Aboriginal languages survive, and there is at least one instance of a language's being revived, namely Dyaabugay in Queensland. There are also attempts at reclamation of languages no longer spoken, but the materials available for many languages, particularly in the southeast of the continent, are inadequate, and the best that future generations can hope for is to learn about their languages rather than acquire their languages. Some languages that are still spoken are undergoing drastic changes. Modern Tiwi, for instance, is much more analytic than traditional Tiwi, which is polysynthetic. For many Aborigines in the north of the continent, a creole is the first language – Torres Strait Broken (Torres Strait Creole), for example, spoken on Cape York, or Kriol in the Kimberleys and the Northern Territory. These creoles have a lexicon largely from English, with an admixture of vernacular vocabulary. They have some claims to being Aboriginal languages, not only on the grounds that they serve to mark Aboriginal identity but also in that they embody traditional semantic concepts that are calques from the vernaculars.

For most Australians, Aboriginal languages are a closed book, though there is a testimony to their existence in a few hundred words borrowed from Aboriginal languages – including *kangaroo* (Guugu-Yimidhirr, Guguyimidjir), *boomerang* (Dharuk), and *dingo* (Dharuk) – and thousands of place names, including Geelong (*tjilang* 'tongue'), Warrnambool (*warnam-bul* 'having fire'), and Wagga-Wagga (*waga-waga* 'crows').

Australian Lexicography

C Yallop, Macquarie University, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

English-speaking people began to colonize Australia in 1788 and soon dominated the entire territory. Separate British colonies joined to form a federation, the Commonwealth of Australia, in 1901. A distinctive variety of English had probably emerged by the 1830s in Sydney, the oldest city, but the local accent and colloquial vocabulary were long regarded as substandard.

Edward Ellis Morris (1843–1902, a professor at the University of Melbourne) should probably be considered Australia's first lexicographer. His *Dictionary of Austral English*, published by Macmillan,

including rituals, during periods of mourning when speech is proscribed, in conversing over long distances, or in hunting, where silence is important.

The Future of Australian Languages

Only a score or so of Australia's native languages are being passed on to the next generation. Over the past three decades, there have been bilingual programs aimed at helping Aboriginal languages survive, and there is at least one instance of a language's being revived, namely Dyaabugay in Queensland. There are also attempts at reclamation of languages no longer spoken, but the materials available for many languages, particularly in the southeast of the continent, are inadequate, and the best that future generations can hope for is to learn about their languages rather than acquire their languages. Some languages that are still spoken are undergoing drastic changes. Modern Tiwi, for instance, is much more analytic than traditional Tiwi, which is polysynthetic. For many Aborigines in the north of the continent, a creole is the first language – Torres Strait Broken (Torres Strait Creole), for example, spoken on Cape York, or Kriol in the Kimberleys and the Northern Territory. These creoles have a lexicon largely from English, with an admixture of vernacular vocabulary. They have some claims to being Aboriginal languages, not only on the grounds that they serve to mark Aboriginal identity but also in that they embody traditional semantic concepts that are calques from the vernaculars.

For most Australians, Aboriginal languages are a closed book, though there is a testimony to their existence in a few hundred words borrowed from Aboriginal languages – including *kangaroo* (Guugu-Yimidhirr, Guguyimidjir), *boomerang* (Dharuk), and *dingo* (Dharuk) – and thousands of place names, including Geelong (*tjilang* 'tongue'), Warrnambool (*warnam-bul* 'having fire'), and Wagga-Wagga (*waga-waga* 'crows').

Australian Lexicography

C Yallop, Macquarie University, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

English-speaking people began to colonize Australia in 1788 and soon dominated the entire territory. Separate British colonies joined to form a federation, the Commonwealth of Australia, in 1901. A distinctive variety of English had probably emerged by the 1830s in Sydney, the oldest city, but the local accent and colloquial vocabulary were long regarded as substandard.

Edward Ellis Morris (1843–1902, a professor at the University of Melbourne) should probably be considered Australia's first lexicographer. His *Dictionary of Austral English*, published by Macmillan,

London, in 1898 (republished by Sydney University Press in 1972), was an informative record of Australian and New Zealand usage, well supported by citations. Most of Ellis's entries were names of flora and fauna, but other vocabulary was not neglected. Local uses of words such as *currency* and *station* were included.

A later and rather different work is Sidney J. Baker's *The Australian Language* (Angus & Robertson, Sydney, 1945; later editions published by Currawong, Sydney, 1966 and 1978). The book was not strictly a dictionary but a lively account of various areas of vocabulary, in which Baker tended to emphasize colloquialisms and Australianness.

A more measured and more conventionally lexicographical treatment of colloquial Australian English is G. A. Wilkes's *A dictionary of Australian colloquialisms*, first published by Sydney University Press in 1978, but reprinted several times. It was most recently published by Oxford University Press in 1996. Various other Australian dictionaries of slang, some well researched, some less so, are on the market.

The first Australian dictionary offering a general coverage of Australian English – that is, including words shared with other parts of the English-speaking word as well as Australianisms – was Oxford University Press's *Australian pocket Oxford dictionary*, edited by Grahame Johnston and published in 1976.

In the 1970s, major lexicographical work began under the leadership of Arthur Delbridge, Professor of English (later of Linguistics) at Macquarie University in Sydney. *The Macquarie Dictionary* appeared in 1981, edited by Delbridge and J. R. L. Bernard, D. Blair, and W. S. Ramson, and published by Macquarie Library. It broke new ground in **not** labeling Australianisms; Australian usage and Australian pronunciations were considered to be the norm. Revised editions (with Delbridge, Bernard, and Blair joined by other editors) appeared in 1990 and 1997. The two-volume Federation Edition, published in 2001, has about 120,000 primary headwords, including encyclopedic entries. Some (by no means all) definitions are accompanied by citations.

In 1988, Oxford University Press published a historical dictionary, *The Australian national dictionary: a dictionary of Australianisms on historical principles*. Edited by W. S. Ramson, it listed only Australianisms (about 6000 headwords) but with plenty of citations in the Oxford manner (about 60 000 in all).

Oxford continues to publish Australian dictionaries with general coverage, under the editorship of Bruce Moore: the *Australian pocket*, for example, reached its fifth edition in 2002. Both Oxford and Macquarie publish a range of related volumes, such as concise and compact dictionaries, and thesauri. HarperCollins also has a range of Australian dictionaries, its largest being *Collins Australian Dictionary* (fourth edition, 2003). Collins, Macquarie, and Oxford dominate the dictionary shelves of most bookshops in Australia.

There are two dictionary research centers at Australian universities: the Australian National Dictionary Research Centre, jointly funded by Oxford University Press and the Australian National University, Canberra; and the DRC (Dictionary Research Centre) at Macquarie University in Sydney. AUSTRALEX, the Australasian Association for Lexicography, was founded in 1990.

Austria: Language Situation

J R Rennison, University of Vienna, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Austrian German

Up to 1918, Vienna was the capital of the Austro-Hungarian Empire and had never been politically united with Germany. The accepted norm was *Schönbrunner Deutsch* (*Schönbrunn* being the court and residence of the Emperors). This variety differs from present-day German Standard German (henceforth GSG) by including several features from the eastern Austrian dialects, for example:

Hat sie gelacht? 'Did she laugh?'
GSG: [hat zi gəlaxt]
Schönbrunner Deutsch: [hɔts glɔxt]

Here we see the typical features of elision of unstressed vowels (schwa in the past participle prefix *ge-* and of /i/ in the pronouns *sie, Sie*), and the rounding of /a/ to [ɔ] (which affects most, but not all lexical /a/s). In addition, Schönbrunner Deutsch typically had /ərl/ as its diminutive suffix and often [a] for umlauted [ɛ], for example:

Glas 'glass (as a material)' vs. *Gläschen/Glaserl* 'glass (for drinking)'
GSG: [glas] – [glɛ:sçən]
Schönbrunner Deutsch: [glas] – [gla:zərl]

An additional, often-cited characteristic of Schönbrunner Deutsch is that everything is pronounced slightly nasalized.

The dialects of Austria fall into two major groups, the Allemanic dialects in the eastern third of the country (in the Province of Vorarlberg) and the Southern Bavarian dialects in the rest of the country. The Allemanic dialects are akin to the dialects of Switzerland and southeastern Germany (Swabia), and the Southern Bavarian dialects to those of southwestern Germany (Bavaria).

Minority Languages in Austria

The minority languages in Austria are Croatian, Slovene, Hungarian, Czech, Slovak, and Gypsy (Roma and Sinti). The official national minorities of Austria are the Burgenland Croats, Slovenes, Hungarians, Czechs, Slovaks, and Roma. Each of these ethnically or politically-historically defined groups corresponds to a single language spoken by its members. Yiddish was formerly spoken in the Jewish community, especially in Vienna, and disappeared when emigration and Nazi genocide forcefully removed its speakers between *c.* 1930 and 1945.

All of the present-day minority languages of Austria are spoken by more people outside Austria than inside the country.

Croatian (*Burgenlandkroatisch*) is mainly spoken in parts of the southeastern province of Burgenland. The number of Croatian speakers according to official censuses has fallen from 43 633 in 1910 to 17 730 in 2001. In view of the unfriendly official policy toward minorities in the past, it is safe to assume that the actual numbers are considerably higher.

Slovene is spoken in the southern provinces of Carinthia (*Kärnten*) and Styria (*Steiermark*) by 50 000 speakers (estimated; census figure 20 000).

Hungarian is also spoken in parts of southeastern Burgenland, but also in Vienna and Graz, by an estimated 25 000 people.

Czech was formerly the language of household personnel, craftsmen, shopkeepers, and publicans in Vienna at the time of the Austro-Hungarian Empire. They were brought in because they were considered to have greater skills than the local workers, especially in the gastronomic area. After 1918, Czech speakers gradually either returned to Czechoslovakia or assimilated into the German-speaking community and gave up their original language. Although still officially a minority, there are now probably far fewer speakers of Czech in Austria than of Serbo-Croatian and Turkish. One legacy of this minority is the high proportion of Czech surnames among German-speaking Austrians in and around Vienna. Today this minority has up to 20 000 speakers (estimated; census figure 8000).

Slovak has long been spoken by a very small minority (estimated at 5000; census figure 1600) in Vienna and to its northeast, up to the Slovakian border.

Gypsy (Roma and Sinti) is an awkward term in German, which perhaps reflects the problematic relationship between Gypsy and German speakers. The German term corresponding to Gypsy is *Zigeuner* (for a male person) or *Zigeunerisch* (for the language); but this is considered derogatory because of a folk etymology that derives this word from *ziehende Gauner* 'wandering crooks.' So the names of two groups of Gypsies, i.e., Roma and Sinti, are used instead. They are found in Burgenland, in and around Vienna, and also in other towns throughout Austria.

An Austrian Minority in Italy

Historically, the area known as the Tyrol (*Tirol*) comprised North, East, and South Tyrol. When the Austro-Hungarian empire was dissolved after the First World War, South Tyrol became a part of Italy.

The majority of people in this area still speak their own dialect of German.

Austric Hypothesis

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Austric is the name given by the German missionary priest Wilhelm Schmidt (1906: 81–82) to the hypothesis that the Austronesian and Austro-Asiatic language families (also first named by Schmidt) are genetically related. Other versions of the hypothesis either include or exclude the Tai-Kadai language family of Southeast Asia, and/or the Hmong-Mien language family. The term 'Macro-Austric' is sometimes applied to a phylum which includes the Hmong-Mien language family.

The possible relationship of an Austro-Asiatic language, Nicobarese, with languages in what was then known as Malayo-Polynesian was first proposed in the latter part of the 19th century, but it was Schmidt who made the first systematic comparison of the two families, citing a considerable number of lexical comparisons, and claiming "complete agreement in phonology, morphology and various features of the syntax." Most of the lexical similarities cited by Schmidt have since been rejected by linguists (Diffloth, 1994) as not being adequately supported by regular sound correspondences. Nevertheless, the search for possible lexical cognates between the two language families continues. The most ambitious work in recent times has been that of Hayes (1999, and earlier works). However a careful review (Reid, 2004) of Hayes's proposed basic vocabulary comparisons revealed that only a very small percentage are probable cognates supported by the usual requirements of regular sound correspondences and semantic similarity.

As for their phonology, morphology, and syntax, it is clear from the extensive descriptive materials that have been published since Schmidt's time that there is certainly not the "complete agreement" that Schmidt claimed for them. However, there are a number of puzzling similarities which call for explanation, especially when Nicobarese is considered. The aspect of Nicobarese that first stimulated Schmidt and others to note its similarities to Austronesian was not only that the language was typologically similar to languages such as Malay (with which they usually compared it) in having prefixes, infixes, and suffixes attached to verbs, but that the form and function of these affixes in many respects appeared to be similar to those in many Austronesian languages. Some of these features were first discussed by Schmidt (1916), and were expanded on in Reid (1994, 1999). Much of the following discussion is based on these two papers.

Typologically, Nicobarese is unlike other Austro-Asiatic languages in being a verb-initial language. In many respects it appears to be an Austronesian language with Austro-Asiatic lexicon. It has been generally characterized as SVO (Schmidt, 1906); however, text materials show numerous examples of VOS word order, found for example in Tagalog, Malagasy, and other Austronesian languages. Noun phrase structure in Nicobarese is also strikingly similar to that found in many Austronesian languages, with noun-attribute word order, and attributes such as relative clauses linked to their head nouns with a form *na*, which commonly occurs in Austronesian languages with identical function. The same form also links adverbial attributes to their head verbs, just as in Austronesian. Noun phrases are introduced by one of a set of distinct case-marking forms, some of which have identical shape and function

The majority of people in this area still speak their own dialect of German.

Austric Hypothesis

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Austric is the name given by the German missionary priest Wilhelm Schmidt (1906: 81–82) to the hypothesis that the Austronesian and Austro-Asiatic language families (also first named by Schmidt) are genetically related. Other versions of the hypothesis either include or exclude the Tai-Kadai language family of Southeast Asia, and/or the Hmong-Mien language family. The term 'Macro-Austric' is sometimes applied to a phylum which includes the Hmong-Mien language family.

The possible relationship of an Austro-Asiatic language, Nicobarese, with languages in what was then known as Malayo-Polynesian was first proposed in the latter part of the 19th century, but it was Schmidt who made the first systematic comparison of the two families, citing a considerable number of lexical comparisons, and claiming "complete agreement in phonology, morphology and various features of the syntax." Most of the lexical similarities cited by Schmidt have since been rejected by linguists (Diffloth, 1994) as not being adequately supported by regular sound correspondences. Nevertheless, the search for possible lexical cognates between the two language families continues. The most ambitious work in recent times has been that of Hayes (1999, and earlier works). However a careful review (Reid, 2004) of Hayes's proposed basic vocabulary comparisons revealed that only a very small percentage are probable cognates supported by the usual requirements of regular sound correspondences and semantic similarity.

As for their phonology, morphology, and syntax, it is clear from the extensive descriptive materials that have been published since Schmidt's time that there is certainly not the "complete agreement" that Schmidt claimed for them. However, there are a number of puzzling similarities which call for explanation, especially when Nicobarese is considered. The aspect of Nicobarese that first stimulated Schmidt and others to note its similarities to Austronesian was not only that the language was typologically similar to languages such as Malay (with which they usually compared it) in having prefixes, infixes, and suffixes attached to verbs, but that the form and function of these affixes in many respects appeared to be similar to those in many Austronesian languages. Some of these features were first discussed by Schmidt (1916), and were expanded on in Reid (1994, 1999). Much of the following discussion is based on these two papers.

Typologically, Nicobarese is unlike other Austro-Asiatic languages in being a verb-initial language. In many respects it appears to be an Austronesian language with Austro-Asiatic lexicon. It has been generally characterized as SVO (Schmidt, 1906); however, text materials show numerous examples of VOS word order, found for example in Tagalog, Malagasy, and other Austronesian languages. Noun phrase structure in Nicobarese is also strikingly similar to that found in many Austronesian languages, with noun-attribute word order, and attributes such as relative clauses linked to their head nouns with a form *na*, which commonly occurs in Austronesian languages with identical function. The same form also links adverbial attributes to their head verbs, just as in Austronesian. Noun phrases are introduced by one of a set of distinct case-marking forms, some of which have identical shape and function

with those found in Austronesian languages. In morphology, there are a number of affixes, such as the causative prefix *ha-* (from earlier **pa-*), the agentive affixes *<um>* and *ma-* / *<am>*, the nominalizing infixes *<an>* and *<in>*, and the objective suffix *-a*, which are taken to be cognate with Austronesian affixes with the same or similar shape, and similar if not identical functions.

The main alternative explanation that has been proposed by those who reject a genetic relationship to account for these facts is borrowing. The claim has been made that the morphosyntactic features found in Nicobarese that appear to be Austronesian are probably remnants of a language spoken by early Austronesian sailors who may have made frequent landfall in the Nicobars, perhaps in some cases staying, intermarrying, and influencing the local language. But there remain several strong barriers to acceptance of this position. One is that several of the proposed comparisons between Nicobarese languages and Austronesian are not limited to Nicobarese, but are found across wide areas of the Austro-Asiatic family. In some cases (especially *<um>* and *<in>*), comparisons are clearest between Nicobarese and Austronesian, because other eastern Austro-Asiatic languages have either lost the form (in the case of verbal suffixes) or modified them due to the strong areal influence of Chinese. Another argument against the borrowing scenario is that some of the forms that are apparently of Austronesian origin predate Proto-Malayic and had changed by the time Austronesian sailors could have reached the Nicobars. A third argument against the borrowing hypothesis that has been proposed is that it is highly unlikely that a language could borrow so much morphology without also borrowing any of the lexical forms which carried it.

The only other possible explanation, according to Reid (1994), is a genetic one. The claim is that Nicobarese is a very conservative Austro-Asiatic language, a classic example of a 'relic' language because of its geographic isolation, lying far off the coast of mainland Southeast Asia, uninfluenced by the leveling influences of Chinese and subsequently Thai that have produced the set of areal features commonly found in Mon-Khmer and other Austro-Asiatic languages. Nicobarese therefore is considered to reflect much of what must be reconstructed for the morphology and syntax of Proto-Austro-Asiatic and ultimately Proto-Austric.

Despite the lack of verifiable lexical comparisons and sustainable sound correspondence sets, some linguists still believe the Austric hypothesis has merit, considering the fairly substantial body of morphosyntactic evidence outlined above. Blust (1996) even proposes a homeland for Proto-Austric, in the general area of the watersheds of the Salween, Mekong and Yangtze rivers in the upper Burma-Yunnan border area. He claims that pre-Austronesians separated from this homeland around 7000 B.C., gradually moving down the Yangtze River valley till they reached the coast, and eventually sailed south and across the Taiwan Strait to Formosa. These proposals, however, have not been widely accepted.

The most recent challenge to the Austric hypothesis has come from Sagart (2004), who proposes an alternative genetic relationship for Austronesian. He claims that Austronesian is most closely related to Sino-Tibetan, and that at least some of the morphological features that appear to support the Austric hypothesis were present also in the parent of Sino-Tibetan-Austronesian, and therefore possibly give evidence of a relationship with Austro-Asiatic at a much greater time depth.

Austro-Tai Hypotheses

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Austro-Tai is the name given to the hypothesis that the Austronesian language family and the Tai-Kadai language family are genetically related. Austronesian languages are primarily spoken in Taiwan, island Southeast Asia and the Pacific, while Tai-Kadai languages are spoken in mainland Southeast Asia, specifically South China, Vietnam, Laos, Thailand, Burma, and Assam (India). Siamese, or Thai, the national language of Thailand, is the best-known Tai-Kadai language and the largest in terms of numbers of native speakers. Lexical similarities between Thai and the Austronesian languages have long been recognized (Schlegel, 1901). However, the hypothesis that the language family to which Thai belongs is genetically related to Austronesian was first proposed by Benedict (1942). Benedict proposed that the genetic relationship between the two language families was a sister relationship, implying that the Tai-Kadai languages are the descendant languages of a parent language – Proto-Austro-Tai – from which pre-Austronesian peoples split in a move to Taiwan, where Proto-Austronesian developed.

Although his later work (Benedict, 1975) was well received by archaeologists and prehistorians, it was generally less well received by linguists, who were skeptical of the extensive array of Proto-Austro-Tai reconstructions that he proposed and his unorthodox methodology for reconstructing them. A number of critical reviews of his work appeared (esp. Gedney, 1976), casting doubt on the nature of the relationship, and pointing to a number of unrecognized loans from Chinese. But the presence in the Tai-Kadai family of a considerable number of forms from the area of basic vocabulary that are very similar in sound and meaning to corresponding Austronesian forms removes the possibility of coincidence as a possible explanation for the similarities. Whether the similarities reflect a genetic relationship or are the result of contact was examined by Thurgood (1994). He concluded that the sound correspondences and tonal developments within the Tai-Kadai languages of forms with comparable Austronesian reconstructions are irregular and thus cannot be evidence of a genetic relationship, but rather of an early contact relationship.

A recent reexamination (Ostapirat, 2000) of the whole question of the internal relationships within the Tai-Kadai family of languages (renamed by Ostapirat as Kra-Dai) has opened up once again the nature of the relationship that exists between this family and Austronesian. In an insightful paper, Ostapirat (2005) presented a list of some 50 pan-Kra-Dai basic vocabulary items, at least half of which can be related by regular sound correspondences to equivalent forms in Proto-Austronesian. The English glosses of Kra-Dai forms that appear to be related to Austronesian include the following: *bear* (n.), *bird*, *black*, *child*, *eat*, *excrement*, *eye*, *far*, *fire*, *grandmother*, *grease*, *hand*, *head*, *I*, *leaf*, *leg*, *live*, *louse (head)*, *moon*, *nose*, *raw*, *sesame*, *shoulder*, *this*, *tooth*, *water*, and *you*.

From this evidence, Ostapirat concluded, "It does not seem likely that the very high number of roots between Kra-Dai and Austronesian that emerge from the core list could be accidental or simply result from borrowings." In commenting on Thurgood's claims that there are no regular sound correspondences between the Kra-Dai and Austronesian families, Ostapirat explained that they are the result of Thurgood's being unaware of crucial data from little-known languages, and of the inadequacy of some of his Proto-Kra-Dai reconstructions. Despite the apparent strength of the evidence he cited, Ostapirat nevertheless considered the evidence to be debatable as proof of a genetic relationship between the families.

An alternate hypothesis regarding the external relationships of the Kra-Dai family is that the languages are genetically related not to Austronesian, but to the Sino-Tibetan family. Ostapirat rejected this hypothesis, noting that etyma that appear to be related to Chinese are rarely found in all branches of the family and almost none belong to the core vocabulary of the language.

The most recent view of the external relationships of the Kra-Dai family is that proposed by Sagart (2005). Building on the comparisons established by Ostapirat, Sagart presented data from a recently described language of the Kra group, Buyang (BYU) (Li, 1999), which apparently, alone, among the Kra-Dai family, retains a number of disyllabic forms which correspond to Proto-Austronesian or Proto-Malayo-Polynesian (PMP) reconstructions, such as BYU ma^{0} $tɛ^{54}$ 'die' (PMP *matay); BYU ma^{0} ta^{54} 'eye' (PMP *mata); BYU qa^{0} $ðu^{11}$ 'head' (PMP *quluh); BYU ma^{0} $ðu^{312}$ 'eight' (PMP *walu), etc.

Data such as these establish beyond any doubt that a genetic relationship exists between the two families. The nature of the relationship, however, is still being discussed. Sagart rejected the possibility that Proto-Kra-Dai and Proto-Austronesian are sister languages, thereby rejecting the Austro-Tai hypothesis in its original formulation. He claimed instead that the Kra-Dai languages are a subgroup of Austronesian, being descendants of the language spoken by a group of Austronesian-speaking people who returned to the mainland from the east coast of Taiwan, long after the first Austronesian settlement there, but probably before the movement south to the Philippines some 4000 years ago of the ancestors of the Extra-Formosan, or Malayo-Polynesian, languages.

Ostapirat stated that if Kra-Dai were a subgroup within Austronesian, as Sagart believes, it would seem likely that they must have belonged to one of the primary branches, in that Proto-Kra-Dai retains a distinction between the reflexes of Proto-Austronesian *C and *t, and *N and *n, pairs of sounds which fell together and are therefore not distinguished in Proto-Extra-Formosan. Moreover Proto-Kra-Dai retains a sibilant reflex of Proto-Austronesian *S, which developed as *h in Proto-Extra-Formosan. In addition, he noted that although there are no Extra-Formosan languages which have reflexes of Proto-Austronesian *Cumay 'bear (n.),' the form is reflected in Kra-Dai languages.

Sagart's position, on the other hand, is that the ancestors of the Kra-Dai languages must have returned to the mainland about the time that the ancestors of the Extra-Formosan languages moved south, in that they apparently reflect certain forms, such as *-mu 'you (sg.),' *lima 'five,' *manuk 'chicken,' etc., that Sagart believes are reconstructible only to the parent of the Extra-Formosan languages, but not to Proto-Austronesian.

If the speakers of the parent of Proto-Tai-Kadai did in fact return to the mainland from Taiwan as proposed by Sagart, he suggests that they probably settled in coastal areas in Guangdong or Guangxi, and their language was eventually relexified by a language from some probably extinct phylum, but one ultimately related to Austroasiatic, retaining only the most basic elements of its Austronesian lexicon.

Austroasiatic Languages

G D S Anderson, Salem, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

The Austroasiatic languages are spoken in small, often remote and inaccessible, hilly or mountainous regions throughout Southeast Asia, as far west as central India and as far east as Vietnam. There are over 150 languages belonging to the numerous Austroasiatic subgroups, enumerated below.

The primary split in the family is between the Munda languages in central and eastern India and the rest of the family. While lexically it is clear that Munda belongs to Austroasiatic, structurally the highly synthetic Munda languages are radically different from their predominantly isolating sister languages to the east. There are two major Munda subgroups, North Munda and South Munda (*see* **Munda Languages**).

Nahali (Nihali), an enigmatic group who speak a language that may or may not belong to Austroasiatic, are now mostly living as subjects to the North Munda Korku in the Indian states of Madhya Pradesh and Maharashtra. Some consider Nahali to have a special relation to Munda, others consider it to be a separate but related group of Austroasiatic, a third faction consider Nahali to be an isolated group in South Asia, like Burushaski (*see* **Burushaski**), while a fourth group of researchers reject Nahali as an independent language, rather considering it to be some kind of thieves' argot or secret language. Exact numbers of speakers are hard to gauge but may be around 5000.

There are at least three other major subgroups of Austroasiatic, the internal relations of which are still a subject of dispute. One such group is Nicobarese, which consists of a small number of languages spoken in the various Nicobar Islands, which lie off the southeastern coast of India, to which they belong administratively. Among this group of languages, Car Nicobarese, Nancowry Nicobarese or Central Nicobarese have received the most amount of linguistic investigation. One language, Shompeng (Shom Peng), appears be highly divergent within the group, but the materials on this language remain scanty. Other Nicobarese languages include Southern Nicobarese, Chaura (Chowra), and Teressa. Published sources include Radakrishnan's (1981) study of Nancowry morphology, among others. The total number of speakers of all Nicobarese languages is likely less than 25 000.

The next major subgroup of Austroasiatic is the Aslian group, which is spoken primarily in Malaysia (where the speakers are known as Orang Asli) but also in adjacent areas of Thailand. Ethnoracially, the Orang Asli of Malaysia fall into three subgroups: the Semang/Negrito, the Sakai/Senoi, and the Jakun/Aboriginal Malay (Parkin, 1991: 41). The first option in each case was traditional but has now become stigmatized, and the latter variant is now preferred. (Note that curiously the Semang/Negrito speakers prefer Sakai, although this is considered offensive to those whom it originally designated; cf. Parkin, 1991: 42.) Only two Jakun/Aboriginal Malay groups speak Aslian languages, Semelai and Temoq. Importantly, the linguistic subgroups of Aslian do not correspond neatly (although partially) to this ethnoracial categorization. In particular, there appears to be a primary split between a southern group (Semelaic (Semelai)) a northern, and a central subgroup (Jahaic (Jehai) and Senoic, respectively). Jah Hut may constitute an isolate branch within Aslian, although others consider it a divergent member of the Senoic subgroup. The exact relation between these subgroups remains to be worked out explicitly. Jahaic includes Negrito groups as well as racially Senoic Chewong. Jahaic languages are mainly spoken by very small groups of a few hundred speakers at most. None could be described as well known, but the subgroup includes such languages as Kintaq (Kintaq Bong), Minriq, Mintil, Jehai (Jahai), Batek, Tonga/Mos, which is mainly spoken in Thailand, Kensiu, and probably the Lowland Semang of Sumatra, with nearly 10 000 speakers. Senoic languages consist of several subgroups. The most important of these are the Lanoh, the poorly known Sabüm, the Temiar, and especially the Semai, who are the largest Aslian-speaking group with possibly as many as 20 000 speakers. Temiar, with perhaps 10 000 speakers, has been an important loan source for Jahaic languages, and is one of the best-studied members of this group (Carey, 1961; Benjamin, 1976). The Semelaic (South Aslian) branch consists of a small number of languages, each of which has probably fewer than 2000 speakers. In addition to Semelai and Temoq, the languages include Semaq Beri and Maq Betiseq (Besisi), also known as Mah Meri. Semelai has recently become the best studied of all Aslian languages with the publication of a large grammar by Nicole Kruspe (2004).

The fourth and final major subgroup within Austroasiatic is the far-flung Mon-Khmer group. This has a number of different subgroups, the internal relations of which remain to be adequately worked out. Major languages in this subgroup include Khmer (Cambodian, Khmeric), Mon (Monic), Vietnamese

(Viet-Muong), Khasi (Khasic), Bahnar (Bahnaric) [BDQ], Kuy (Katuic), Palaung (Palaung-Wa), including Pale, Rumai, and Shwe, and so forth (*see* **Mon-Khmer Languages**).

Generally speaking, the westernmost languages of the family exhibit the greatest degree of morphological development. Munda languages are inflectional and agglutinating, with a diverse and highly developed system of tense/aspect marking, subject and object agreement, noun incorporation, and so on. An extreme example of this comes from Kharia, where the following word has no fewer than 8 morphemes:

(1) *Kharia*
ḍoḍ-kay-ṭu-ḍom-bhaʔ-goḍ-na-m
carry-BEN-TLOC-PASS-quickly-COMPLT-FUT-2
'get yourself there for me quickly'
(Malhotra, 1982)

Tense/aspect morphology is not common among non-Munda Austroasiatic languages but may be found in Lyngngam of the Khasic branch of Mon-Khmer (*see* **Khasi**) and in certain Bahnaric and Katuic languages. In addition to Munda, certain Aslian languages show subject agreement in the verb, but otherwise this feature is not a common one in Austroasiatic.

South Munda and Nicobarese, and to a lesser extent the Aslian language Temiar, reflect evidence of noun incorporation, and this may therefore have been a feature of earlier stages of the Austroasiatic language family.

(2) Temiar
pasal-naq ki-chiibjuq
reason-that 1PL-walk < *'go.foot'
'so we had to go on foot'
(Carey, 1961: 46)

It seems certain that Proto-Austroasiatic was richer morphologically than the majority of Mon-Khmer languages, particularly in terms of derivation, but not as developed as the Munda languages. Among the more noteworthy features of Austroasiatic is the unusually frequent use of infixation processes. A small number of derivational elements appear to be cognate across the members of the family, for example, a causative verb formant and a nominalizing element. The former appears either as a prefix or an infix, depending on the stem shape. Both elements are found in such branches as Munda, here exemplified by Juang Nicobarese, and the Mon-Khmer subgroups Monic and Khmuʔic (Khmuic), while other branches preserve only the prefix allomorph.

(3) Juang
a'b-soŋ
CAUS-buy
'sell'
(Pinnow, 1960a)
< *kɔsɔr*

Juang
kɔ-'b-sɔr
dry..-CAUS-..dry
'dry sthg'

(4) Nancowry
ha-kah-naŋ
CAUS-know-ear
'make understand'
(Radakrishnan, 1981: 87)

Nancowry
p-um-lóʔ
lose-CAUS-lose
'make lose'
(Radakrishnan, 1981: 54)
< *plóʔ*

Another infixation process found across the langauges of the Austroasiatic stock is the nominalizing infix -n-. This is found in such forms as Khasi *shnong* 'village' < *shong* 'live,' Mlabri *chnrɛɛt* 'comb' < *chrɛɛt* 'to comb,' or Mundari *dunub* 'meeting' < *dub* 'sit.'

It has been put forth that Austroasiatic may be a part of a larger genetic unit. Various proposals include relations with Austronesian, Tai-Kadai, Hmong-Mien (Miao-Yao), and even Sino-Tibetan, variously labeled 'Austric,' Austro-Tai, and so on. None of these proposals are widely accepted by specialists, and these hypotheses should therefore be treated with caution. Among modern specialists in Austroasiatic languages, Gerard Diffloth deserves special mention.

Austronesian Languages: Overview

T Crowley[†], University of Waikato, Hamilton, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

The Language Family and Its Speakers

Austronesian is possibly the largest language family in the world. Its 1200 or so languages (Grimes *et al.*, 1994: 122) amount to about a fifth of the world's total number. While the Niger-Congo family is sometimes said to be larger than Austronesian by a couple of hundred languages, it is by no means a well-established grouping, and some have suggested that it is merely a typological rather than a genetic grouping. The lower-level Benue-Congo grouping (*see* **Benue-Congo Languages**) is much better established, but it has about 200 fewer languages than the Austronesian family. Austronesian is way ahead of the next grouping, the Trans New Guinea languages, which has fewer than 600 members. However, Austronesian again constitutes a much more clearly recognizable family than the Trans New Guinea grouping.

Austronesian languages represent the fourth-largest grouping of languages in the world in terms of the number of speakers. According to some, they are beaten again by Niger-Congo languages, relegating them to fifth position, though the relatively poorly supported claims about the genetic unity of these languages means that the fourth position for Austronesian should perhaps be maintained. The total number of speakers of Austronesian languages is about 300 million, which represents about 5% of the world's population. The Austronesian family includes the world's 13th-largest individual language (Javanese) in terms of the number of native speakers. Malay/Indonesian (*see* **Malayo-Polynesian Languages**) and Tagalog (spoken in the Philippines) (*see* **Tagalog**) come in at 9th and 18th respectively in terms of the total number of first- and second-language speakers (Crystal, 1987: 287). No putative

Austronesian Languages: Overview

T Crowley[†], University of Waikato, Hamilton, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

The Language Family and Its Speakers

Austronesian is possibly the largest language family in the world. Its 1200 or so languages (Grimes *et al.*, 1994: 122) amount to about a fifth of the world's total number. While the Niger-Congo family is sometimes said to be larger than Austronesian by a couple of hundred languages, it is by no means a well-established grouping, and some have suggested that it is merely a typological rather than a genetic grouping. The lower-level Benue-Congo grouping (*see* **Benue-Congo Languages**) is much better established, but it has about 200 fewer languages than the Austronesian family. Austronesian is way ahead of the next grouping, the Trans New Guinea languages, which has fewer than 600 members. However, Austronesian again constitutes a much more clearly recognizable family than the Trans New Guinea grouping.

Austronesian languages represent the fourth-largest grouping of languages in the world in terms of the number of speakers. According to some, they are beaten again by Niger-Congo languages, relegating them to fifth position, though the relatively poorly supported claims about the genetic unity of these languages means that the fourth position for Austronesian should perhaps be maintained. The total number of speakers of Austronesian languages is about 300 million, which represents about 5% of the world's population. The Austronesian family includes the world's 13th-largest individual language (Javanese) in terms of the number of native speakers. Malay/Indonesian (*see* **Malayo-Polynesian Languages**) and Tagalog (spoken in the Philippines) (*see* **Tagalog**) come in at 9th and 18th respectively in terms of the total number of first- and second-language speakers (Crystal, 1987: 287). No putative

[†]Deceased.

Niger-Congo language appears in the top 20 for either list.

If we exclude the spread of Indo-European languages to the New World in association with colonialism, Austronesian languages also have by far the largest geographical spread of any language family in the world. Their territory extends from the islands of Taiwan and Hawai'i in the north, Easter Island (or Rapanui) in the east, New Zealand in the south, and Madagascar in the west. However, the territory within these bounds is not occupied exclusively by speakers of Austronesian languages, as Australia (*see* **Australian Languages**) and Tasmania, parts of the New Guinea area, and parts of mainland Southeast Asia include a variety of different non-Austronesian languages.

The Austronesian family is noteworthy not just for its largest languages, as it includes a huge number of very small languages as well. The Republic of Vanuatu (*see* **Vanuatu: Language Situation**) – located in the southwest Pacific – has a population of only about 200 000, but its people speak at least 80 separate Austronesian languages (Lynch and Crowley, 2001), giving each language an average population of about 2500 speakers and making Vanuatu possibly the world's most diverse nation in terms of the number of languages per capita.

While Austronesian languages constitute a well-defined linguistic grouping, their speakers are very diverse in terms of physical appearance. People of a variety of Asian types speak Austronesian languages in what is now Indonesia (*see* article **Indonesia: Language Situation**), Malaysia, Singapore, Brunei, the Philippines (*see* Philippines: Language Situation [01736]) and the interior of Taiwan. In the far west in Madagascar, speakers of the Austronesian language Malagasy clearly exhibit African genes. In the Pacific, the Melanesian speakers of Austronesian languages from the island of Timor, the Indonesian province of West Papua, Papua New Guinea (*see* article **Papua New Guinea: Language Situation**), Solomon Islands (*see* article **Solomon Islands: Language Situation**), Vanuatu, New Caledonia, and Fiji differ in appearance from their Asian neighbors to their west, from their Polynesian neighbors to their east, and from their Micronesian neighbors to their north.

In fact, the boundaries between physical types are far from rigid, and there is often a gradual transition from one type to another, as genes have been mixing for centuries. In any case, linguistic boundaries and the boundaries of physical types often fail to coincide. We see this most dramatically in the New Guinea area, where physically similar Melanesian peoples may speak Austronesian languages or any of a number of completely unrelated non-Austronesian languages, including languages belonging to the Trans New Guinea grouping referred to earlier in this article. Sometimes, people in neighboring villages may speak totally unrelated languages. In fact, in the agglomerated village of Hanuabada, in Papua New Guinea, speakers of Austronesian Motu and non-Austronesian Koita (Koitabu) live side by side in the same community.

The Austronesian-speaking area exhibits cultural diversity that is even more dramatic than the diversity of physical types. As an illustration, we could point to the Hindu culture of Bali, in Indonesia; the traditional animist belief systems of Austronesian speakers in Melanesia (which continue to be practiced in some areas); the traditional polytheistic practices of the Polynesians, the Muslims of most of Indonesia, Malaysia, and southern Philippines; and the centuries-old Christian traditions of the central and northern Philippines. In some parts of the Austronesian-speaking world, traditional culture areas may be only slightly larger than the areas occupied by some of the very small individual languages. For instance, on the island of Malakula, in Vanuatu, significant differences in social organization and material culture can be found over quite short distances, with distinct culture areas including only two or three quite small language groups.

Of course, there has been a great deal of relatively recent technological and cultural change throughout the Austronesian-speaking world, with the advent of European colonialism and the modern technological revolution. The changes have perhaps been most dramatic (and most recent) in Melanesia, where in some cases fully traditional practices held sway until the first half of the 20th century. Although there are unlikely to be any more dramatic discoveries of 'lost tribes' who know nothing of the outside world, there are certainly still places where contact has until now been fairly minimal. While Christianity has now been adopted with fervor in most of Melanesia, Micronesia, and Polynesia, this change has often taken place in a way that has allowed for the retention of various aspects of the traditional belief system along with (or as part of) local Christianity.

Internal Genetic Relationships and Reconstruction

Based on the analogy of the naming of the Indo-European family after the geographical extremities – Indian and European languages – the Austronesian languages were originally referred to as Malayo-Polynesian, after Malay (and its relatives) in the west and the Polynesian languages in the east. However, it was subsequently realized not only that the

indigenous Formosan languages of Taiwan belonged in this family but also that these represented several distinct high-level subgroups. The term *Malayo-Polynesian* was then reassigned to cover all of the non-Formosan languages within the enlarged family. This was, henceforth, referred to as Austronesian, based on the elements *Austro-* 'southern' and *-nesia* 'island.' The latter element is, of course, also found in the names for the geographical areas of Polynesia (= many islands, because of the large number of islands involved), Melanesia (= black islands, because they are occupied by dark-skinned peoples), and Micronesia (= small islands, because these are mostly narrow, low-lying atolls).

While the Austronesian languages exhibit a considerable amount of structural diversity, the existence of the language family as a whole is completely uncontroversial, in contrast to that of some other language groupings – including the so-called Niger-Congo languages – where debates rage between 'lumpers' (who seek to link together as many languages on the basis of what sometimes look to others more like typological similarity) and 'splitters' (who are sometimes overcautious in requiring anything but absolutely infallible proof of genetic relationship).

In fact, the idea that Austronesian languages are related is often obvious even to a casual observer, in contrast, again, to many other language groupings where even an experienced linguist might find it difficult to see convincing evidence of a relationship. For example, the root for 'eye' is *mata* in exactly this shape in languages as far apart as Yami (in Taiwan), Tagalog (in the Philippines), Malay/Indonesian, Manggarai (in eastern Indonesia), Manam (in Papua New Guinea), Roviana (in Solomon Islands), Raga (in Vanuatu), and Tongan, Tahitian, and Rapa Nui (on Easter Island). Such lexical similarities are reasonably common in those parts of the vocabulary which we would expect to be most resistant to borrowing – hence strong indicators of genetic relationship – and borrowing is most unlikely, in any case, as an explanation for these similarities, given the huge distances involved.

So readily apparent is the relationship between many of these languages that a connection of sorts between the Polynesian languages and Malay was suggested by Hadrian Reland as early as 1708, when very little indeed was known about most of these languages. Lorenzo Hervas y Panduro in 1784–1787 described a more detailed set of linguistic relationships among Austronesian languages in which the language of Madagascar and a larger number of Indonesian languages were also included (Lynch *et al.*, 2002: 1).

The little-known islands of Melanesia were usually excluded from these original generalizations, perhaps partly because of a mistaken assumption that the physically distinct Melanesian peoples should also be linguistically very distinct. However, it turned out from work in the late 19th century by H. C. von der Gabelentz and R. H. Codrington (Lynch *et al.*, 2002: 2), based largely on information supplied by Christian missionaries in the field, that a substantial number of these languages *do* belong in this family as well. While many of the languages of the New Guinea area are clearly *not* Austronesian, some of the Austronesian languages of Melanesia were originally thought to be non-Austronesian only because extensive phonological changes had obscured the shapes of many widely distributed Austronesian roots, or because extensive lexical innovation had led to the replacement of some of the more widespread Austronesian cognates by which relationship could be most easily recognized. By the end of the 19th century, however, it was realized that a substantial number of indisputably Austronesian languages were in fact spoken in many of the coastal parts of the New Guinea area, as well as in Solomon Islands, Vanuatu, and New Caledonia.

This burgeoning language family was soon to become the most serious early testing ground for the comparative method of phonological and lexical reconstruction that was developed initially on the basis of Indo-European – and, less widely known, Finno-Ugric – languages in the second half of the 19th century. Although Edward Sapir's reconstruction of Uto-Aztecan in 1913–1915 represented a stunning early application of the comparative method to unwritten languages, Otto Dempwolff's (1934, 1937, and 1938) comparative study of the vastly larger Austronesian family represented a much more challenging test of the method.

Of course, a large number of new Austronesian data have become available since Dempwolff's time, and there has also been significant fine-tuning of the comparative method itself. Many of his comparisons were enriched in the work of Isidore Dyen (1951, 1953a, 1953b, 1965) and others from the 1950s, and many new reconstructions have also been proposed. Robert Blust (1970, 1980) has progressively added to the reconstructed lexicon since the early 1970s, bringing the total number of lexical reconstructions now to many thousands of entries. A substantial amount of morphosyntactic reconstruction since the late 1970s can also be ascribed to the level of Proto-Austronesian as a result of work by Stanley Starosta (1985), Lawrence Reid (1978), and others.

Comparative reconstruction has not proceeded solely at the level of Proto-Austronesian, as there has been major effort devoted to lower levels of reconstruction as well. Perhaps the most significant intermediate reconstruction involves the ongoing work since the 1990s of Malcolm Ross *et al*. (1998, 2003) in the reconstruction of Proto-Oceanic, the ancestor of the 500 or so members of the Oceanic subgroup. However, many others have also contributed in this area, beginning with the work of George Grace (1969) and Wilhelm Milke (1968) in the 1960s. Below the level of Proto-Oceanic, there is a tradition of reconstruction of Proto-Polynesian, for which serious comparative work based on a wide selection of languages dates from David Walsh and Bruce Biggs (1966).

With such a huge language family, internal subgrouping could be expected to be a somewhat contentious issue. However, there is now broad agreement on many issues of subgrouping within Austronesian. Work on subgrouping methodology by Malcolm Ross since the 1980s has added new considerations to the subgrouping of Austronesian languages, with his distinction between separation-induced 'subgroups' on the one hand and 'linkages' that have arisen as a result of gradual diversification of dialects that remained in geographical contiguity (Ross, 1988). This distinction allows us to take into account the fact that some lower-level groupings of languages, rather than uniquely sharing a set of defining innovations, may actually overlap with neighboring groupings in that they may appear to share innovations from more than one subgroup.

While new data and fresh approaches to subgrouping methodology may bring about further revisions in the future, the generally accepted current view is that the area of greatest subgrouping diversity is on the island of Taiwan (Lynch *et al*., 2002: 4). Recent research indicates that there may be as many as nine first-order subgroups there (Blust, 1999), with the remaining first-order subgrouping consisting of the Malayo-Polynesian languages, which is made up of the huge number of remaining Austronesian languages.

The western part of the Malayo-Polynesian subgroup appears to consist of a large number of smaller subgroups. This region includes all of the languages of the Philippines, as well as Malaysia and the islands of Indonesia from Sulawesi and Sumbawa westward, and also the Malagasy language of Madagascar. It is in this area that all of the very large Austronesian languages belong, including Tagalog (*see* article **Tagalog**), Sebuano, Ilokano (Ilocano), Hiligaynon, and Bikol (Bicolano) in the Philippines, and Malay/Indonesian, Javanese (*see* article **Javanese**), Sundanese (Sunda), Madura, Minangkabau, Bugis, Balinese (Bali), and Acehnese (Aceh) in Indonesia.

All of the languages to the east of the Western Malayo-Polynesian languages probably belong in a single very large Central and Eastern Malayo-Polynesian subgrouping that consists overwhelmingly of much smaller languages. This subgroup is thought to involve a binary split between a geographically restricted Central Malayo-Polynesian grouping involving the languages of Sumba, Flores, Timor, Buru, Seram, and adjacent smaller islands, and a much larger Eastern Malayo-Polynesian grouping consisting of all the rest. However, the internal subgrouping of both Central and Eastern Malayo-Polynesian and Central Malayo-Polynesian remains poorly understood. Eastern Malayo-Polynesian in turn enters into a binary split between the Southwest Halmahera–West New Guinea languages on the one hand and the very large Oceanic subgroup on the other.

The Oceanic subgroup occupies a special place within Austronesian linguistics. Although this is by no means one of the highest-level subgroups in the family, it is nevertheless a huge grouping, comprising nearly half of all of the Austronesian languages and amounting to nearly 10% of all of the languages of the world. With a total Oceanic-speaking population of about 2 million, the average-sized Oceanic language can claim only about 4000 speakers. Excluding some of the largest Oceanic languages from this total, such as Fijian (*see* article **Fijian**), with nearly 500 000 speakers, the average size for an Oceanic language drops to closer to 3000 speakers. Most of these languages are poorly documented in comparison to languages further west, and many are almost completely undocumented.

Oceanic subgrouping diversity is greatest in the west, with possibly four of the five primary subgroups located in this area: the Admiralties languages; the Western Oceanic languages of the north coast of the Indonesian province of Papua (formerly known as West Papua) and the coast of New Guinea, New Britain, New Ireland, Bougainville, and western Solomon Islands; the St Matthias subgroup; and the Yapese language as a single-language subgroup (Lynch *et al*., 2002: 92–120).

A putative Central and Eastern Oceanic subgroup covers Polynesia and Fiji and all remaining areas of Micronesia and Melanesia, including New Caledonia, Vanuatu, and part of Solomon Islands. Within this very large grouping, there is a five-way split between the Micronesian languages, the languages of southeastern Solomon Islands, the languages of Utupua and Vanikoro in Solomon Islands, the languages of

Vanuatu and New Caledonia, and finally the Central Pacific languages, consisting of Fijian, Rotuman, and the Polynesian languages.

Further conclusions have been presented about subgrouping at even lower levels, with a detailed subgrouping diagram available for the Polynesian languages. Given the size of the Oceanic family within Austronesian, the final family tree diagram is obviously going to be extremely complex. All subgrouping hypotheses will have to be kept 'open' pending further linguistic documentation in poorly known areas. One point that will be obvious, however, is that the geographically expansive and relatively well-described Polynesian languages, which have for more than 200 years figured so prominently in European fantasies about the Pacific, represent just a very small grouping of just over two dozen languages at the very lowest level of Austronesian subgrouping.

Linguistic Features

The huge size of the Austronesian family makes any kind of summary statements about 'typical' features well-nigh impossible. At the same time, the approximately 5000-year time depth for Austronesian languages is relatively shallow compared with language groupings such as Australian languages and Trans New Guinea languages, and the Austronesian family is structurally rather less diverse than such groupings as a result.

Since there are major structural differences between some of the Formosan and Western Malayo-Polynesian languages on the one hand and the Oceanic languages on the other, it is perhaps best to offer several sets of generalizations about widespread linguistic features in Austronesian languages. Even so, it must be recognized that within any such structural groupings, there are many languages that exhibit rather different sorts of patterns, so the patterns that are presented here are those which, in addition to having substantial geographical distribution, also appear to reflect some antiquity in a reconstructive sense.

In terms of phonology, it is particularly difficult to generalize about Austronesian languages. One thing that it is possible to say is that tonal contrasts are almost completely absent, in contrast to the phonological systems of many neighboring Asian languages. Tone is furthermore not reconstructible at all in Proto-Austronesian. While there has long been general agreement on the reconstructed four-vowel system /i u ə a/, there has until recently been much less agreement firstly on the number of consonantal contrasts, and secondly on the precise phonetic value of a number of reconstructed protoconsonants.

Complex sets of consonantal correspondences led scholars in the past to posit consonant inventories varying between two and three dozen segments in total. Arguments were presented, for example, that correspondences pointed to a maximal set of reconstructions involving /d ḍ D D_1 D_2 D_3 d_1 d_2 d_3/, where the symbols represented a mix of phonetic and purely formulaic information (Ross, 1994: 54). These issues of phonetic uncertainty and the proliferation of protoconsonants have now been largely laid to rest (Blust, 1999), though Wolff (2003) remains a dissenting voice. Because the few Formosan languages represent a number of primary subgroups of Austronesian, the relatively recent study of these languages has provided evidence for substantial modifications in both the inventory and the phonetic value of Dempwolff's original phonological reconstructions.

There has been a considerable amount of phonemic merger, split, and shift in many subgroups and in many individual Austronesian languages. There has also been phonological erosion of particular phonotactic positions, particularly involving word-final consonants in Oceanic languages. Original nasal-stop clusters have also been reanalyzed in Oceanic languages as prenasalized stop phonemes, resulting in substantial phonotactic simplification. Some individual languages have undergone other more dramatic phonological changes, including also the reanalysis of other material as part of the root, so reconstructible **mata* 'eye' appears regularly as /nəmrə/ in the Lenakel language of Vanuatu.

In terms of basic clause structure, the languages of the geographical extremities of the Austronesian-speaking areas are typologically very different. The languages of Taiwan and the Philippines exhibit what are often called 'focus' systems, which appear to directly reflect a reconstructible pattern at the Proto-Austonesian level (Ross, 1994: 64–66). In this system, verbs carry inflectional marking – expressed variously as prefixes, suffixes, or infixes or as a combination of more than one of these affixed elements – for so-called Actor Focus (AF), Undergoer Focus (UF), Locative Focus (LF), and Instrumental Focus (IF). The noun phrase that is signaled as being in focus typically appears clause-finally, is definite, and performs a range of possible semantic roles according to the nature of the focus marking on the verb. This is a completely un-English construction for which it is difficult to provide close translations, but examples (1), (2), (3), and (4) from Tagalog illustrate this pattern, based on the verb roots *bili* 'buy,' *tamVn* 'plant,' and *putol* 'cut':

(1) *B-um-ili* *ng* *kotse* *ang* *lalake.*
AF:buy PATIENT car TOPIC man
'The man bought a car.'

(2) *B-in-ili* *ng* *lalake* *ang* *kotse.*
UF:buy AGENT man TOPIC car
'The car was bought by the man.'

(3) *T-in-amn-an* *ng* *lalake* *ng*
LF:plant AGENT man PATIENT
damo *ang* *lupa.*
grass TOPIC ground
'The ground was planted the grass in by the man'–i.e., 'The man planted the grass in the ground.'

(4) *I-p-in-utol* *ng* *lalake* *ng*
IF:cut AGENT man PATIENT
isda *ang* *kutsilyo.*
fish TOPIC knife
'The knife was cut the fish with by the man' – i.e., 'The man cut the fish with the knife.'

Oceanic languages, by way of contrast, evolved a system of formal marking for transitivity on verbs that expresses a range of different semantic roles associated with the verbal object. This marking involves verbal suffixes that express a distinction between unsuffixed transitive verbs with undergoer objects and those that carry a transitive suffix with typically oblique objects. These transitive suffixes are often described as expressing close and distant transitive respectively and are associated with different sorts of semantic roles. Thus, in Fijian the intransitive verb *qasi* 'crawl' corresponds to the close transitive form *qasi-va* 'crawl to (location)' and the distant transitive form *qasi-vaka* 'crawl with (something held).'

Oceanic languages have evolved a wide range of other innovative features from the reconstructible Proto-Austronesian pattern. At the Proto-Oceanic stage, a formal distinction had developed between inalienable and alienable possession, with the former being expressed by means of pronominal suffixes attached directly to a noun and the latter expressed by means of an adposed possessive constituent to which pronominal suffixes were attached (Lynch *et al.*, 2002: 40–41). This distinction is still widely reflected in Oceanic languages in examples such as (5) and (6), from the Naman (Nama) language of Vanuatu:

(5) *khavo-g*
brother-1SG
'my brother'

(6) *neim* *khëso-g*
house POSS-1SG
'my house'

Naman has in fact simplified the reconstructible system for the expression of alienable possession, in that there is now only a single set of adposed possessive constituents. At the Proto-Oceanic stage, there are likely to have been separate possessive forms depending on whether the possessed item was for eating, for drinking, or for any miscellaneous purpose (Lynch *et al.*, 2002: 42). This three-way distinction is still maintained in many Oceanic languages, such as examples (7), (8), and (9), from Fijian:

(7) *na* *me-mu* *wai*
ART DRINK-2SG water
'your water'

(8) *na* *ke-mu* *dalo*
ART ED-2SG taro
'your taro'

(9) *na* *no-mu* *vale*
ART POSS-2SG house
'your house'

In some Oceanic languages, however, a number of additional categories of alienable expression occur. In the Raga language of Vanuatu, for example, in addition to forms expressing edible, drinkable, and miscellaneous possession, there are the possessive constituents *bila-* 'garden plots, crops, domestic animals, personal adornments' and *wa-* 'sugarcane,' and some languages have developed even more categories of alienable possession.

The Polynesian languages have taken the expression of possession in yet another direction. A possessor is preceded by a possessive marker containing either the vowel *a* or *o*. Thus, in Samoan, we find examples such as those in (10) and (11) (Lynch *et al.*, 2002: 43):

(10) *lo-'u* *tama*
POSS-1SG son
'my son'

(11) *la-'u* *naifi*
POSS-1SG knife
'my knife'

Inalienably possessed items generally express possession by means of the *o* forms, while *a* forms tend to correspond to categories of alienable possession in other Oceanic languages. However, there is substantially more arbitrariness and metaphor involved in the interpretation of the alienable-inalienable distinction in these languages. For instance, the possession of canoes in Samoan is considered as being more 'personal' than the possession of a knife, so 'my canoe' is expressed as *lo-'u paopao*.

Historical Interpretation

By combining subgrouping information, the content of the reconstructible lexicon of Proto-Austronesian

(as well as the lexicons of various lower-level subgroups, most significantly Proto-Oceanic), and information provided by the archaeological record, it is possible to come up with a fairly sophisticated picture of Austronesian history dating back at least 5000 years (Bellwood *et al.*, 1995). The story of human settlement of the Pacific Islands has tended to attract the interest of enthusiastic amateurs and religious groups who have been prepared to argue particular points of view in a way that has sometimes attracted a certain amount of broader public acceptance, even though the scientific evidence often points in radically different directions.

Given that the area of greatest subgrouping diversity within a language family is most likely to represent the original homeland, we could argue on these grounds alone that the Austronesian homeland is likely to have been either on Taiwan or on the adjacent mainland of southern China and that there has been a general west-to-east movement, with Polynesia being the last area to be settled. Given that the Polynesian languages represent a linguistically very homogeneous and geographically expansive subgroup, this, on linguistic grounds, would be the least likely source for Austronesian languages. However, that has not prevented people inspired by the *Kon Tiki* expedition from arguing instead for a general east-to-west population movement, beginning in South America.

The view of some religious groups that Polynesian people are descendants of one of the Lost Tribes of Israel is also impossible to reconcile with the fact that there is no linguistic evidence in support of this contention, while there is a huge amount of incontrovertible evidence in support of linguistic relationships between Polynesian languages and those of the rest of the Austronesian-speaking world. And of course, there is a mass of archaeological evidence pointing to the origin of Polynesian peoples from previously settled areas of the Austronesian-speaking world, and none in support of an origin elsewhere (Howe, 2003).

The first major population movement away from the Austronesian homeland was that which took speakers of Proto-Malayo-Polynesian out of the Taiwan area into the Philippines, presumably via an entry point in the north. A series of population movements and associated linguistic splits would have seen this original group spread to the rest of that archipelago and ultimately to all of what is now Indonesia. As part of this series of population movements, the island of Madagascar was settled by a group of people who originated from Kalimantan.

Ultimately, speakers of a language immediately ancestral to Proto-Oceanic moved out of the area of Halmahera and the Indonesian province of Papua into the Oceanic homeland of New Britain and New Ireland approximately 3500 years ago. Melanesia was at the time occupied by speakers of non-Austronesian languages. As early descendants of Proto-Oceanic speakers began to spread, their progress was limited on the mainland of New Guinea to coastal areas, while the hinterland and the distant interior continued to be occupied by speakers of non-Austronesian languages.

However, there was obviously substantial linguistic contact between these two major linguistic groups, as the reconstructible *VO* word order often shifted to *OV* order in this area under the apparent influence of non-Austronesian patterns. A small number of languages – most famously Magori and Maisin of Papua New Guinea – underwent such thoroughgoing influence from non-Austronesian languages that for many years there was dispute as to whether they should be classified as Austronesian or not.

Population movements – and associated linguistic diversification – continued with the eastward drift of Oceanic-speaking groups. Up to this stage, most of the population movements involved relatively short ocean voyages to islands that were clearly visible from neighboring populated islands. However, about 3000 years ago there was a period of sudden geographical expansion out of western Melanesia involving a series of major ocean voyages into what must initially have been unknown and unpopulated territory. These voyages led to settlement as far afield as Tonga and Samoa.

It was in Tonga and Samoa that Proto-Polynesian diverged from its ancestor. From there, an even more dramatic series of oceangoing voyages led to the discovery and settlement of nearly every island group in the Pacific between the time of the birth of Christ and A.D. 1000. It should be kept in mind that this was all happening at a time when Britons were still lumbering across narrow rivers in coracles. It was Polynesian sailors who were the world's first major navigators, rather than the likes of Vasco da Gama, Christopher Columbus, and Captain Cook, whose voyages followed well over 1000 years later.

Possible External Genetic Relationships

The Austronesian languages constitute a very well defined language family in that there are few languages whose status as being Austronesian is in dispute. The status of some languages has been the subject of debate given the possibility of influence from so-called Papuan or non-Austronesian languages in the New Guinea area, and different scholars in the past were uncertain as to whether Maisin and Magori should be treated as non-Austronesian

Figure 1 The Austronesian family and major Austronesian language groups (drawn by Malcolm Ross).

languages or as Oceanic languages (Lynch *et al.*, 2002: 16). While both clearly show evidence of substantial borrowing from non-Austronesian languages, it is now accepted that they can be treated as genuinely Austronesian languages. There are also a handful of languages spoken in the extreme east of Solomon Islands about which there has been some debate in the past; this issue has not yet been definitively resolved.

Most suggestions of relationships between Austronesian languages and other language groupings call for greater willingness to come to conclusions on the basis of relatively little evidence. Some scholars have claimed that there is a relationship between Austronesian languages and Japanese, others between Austronesian and the Tai-Kadai languages of southern China, others between Austronesian and Sinitic languages, and others between Austronesian and Austro-Asiatic languages, such as Nicobarese (Ross, 1994: 95–99). The few similarities between Japanese and Austronesian seem likely, at best, to involve a few very early Austronesian loans into Japanese. The other links may point to a series of relationships within a single very large grouping, though few would regard such a hypothesis as demonstrable.

Just as interesting, of course, is the question of a possible relationship between Austronesian languages and language groupings for which no suggestions of wider relationships have ever been offered. Most significant among these are the Australian languages, which represent a completely separate language family in their own right, and the various 'Papuan' languages of the New Guinea area. So convincing is the lack of relationship between the latter and Austronesian languages that these 'Papuan' languages are often collectively referred to in regional studies simply as non-Austronesian languages.

Austro-Tai Hypotheses

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Austro-Tai is the name given to the hypothesis that the Austronesian language family and the Tai-Kadai language family are genetically related. Austronesian languages are primarily spoken in Taiwan, island Southeast Asia and the Pacific, while Tai-Kadai languages are spoken in mainland Southeast Asia, specifically South China, Vietnam, Laos, Thailand, Burma, and Assam (India). Siamese, or Thai, the national language of Thailand, is the best-known Tai-Kadai language and the largest in terms of numbers of native speakers. Lexical similarities between Thai and the Austronesian languages have long been recognized (Schlegel, 1901). However, the hypothesis that the language family to which Thai belongs is genetically related to Austronesian was first proposed by Benedict (1942). Benedict proposed that the genetic relationship between the two language families was a sister relationship, implying that the Tai-Kadai languages are the descendant languages of a parent language – Proto-Austro-Tai – from which pre-Austronesian peoples split in a move to Taiwan, where Proto-Austronesian developed.

Although his later work (Benedict, 1975) was well received by archaeologists and prehistorians, it was generally less well received by linguists, who were skeptical of the extensive array of Proto-Austro-Tai reconstructions that he proposed and his unorthodox methodology for reconstructing them. A number of critical reviews of his work appeared (esp. Gedney, 1976), casting doubt on the nature of the relationship, and pointing to a number of unrecognized loans from Chinese. But the presence in the Tai-Kadai family of a considerable number of forms from the area of basic vocabulary that are very similar in sound and meaning to corresponding Austronesian forms removes the possibility of coincidence as a possible explanation for the similarities. Whether the similarities reflect a genetic relationship or are the result of contact was examined by Thurgood (1994). He concluded that the sound correspondences and tonal developments within the Tai-Kadai languages of forms with comparable Austronesian reconstructions are irregular and thus cannot be evidence of a genetic relationship, but rather of an early contact relationship.

A recent reexamination (Ostapirat, 2000) of the whole question of the internal relationships within the Tai-Kadai family of languages (renamed by Ostapirat as Kra-Dai) has opened up once again the nature of the relationship that exists between this family and Austronesian. In an insightful paper, Ostapirat (2005) presented a list of some 50 pan-Kra-Dai basic vocabulary items, at least half of which can be related by regular sound correspondences to equivalent forms in Proto-Austronesian. The English glosses of Kra-Dai forms that appear to be related to Austronesian include the following: *bear* (n.), *bird*, *black*, *child*, *eat*, *excrement*, *eye*, *far*, *fire*, *grandmother*, *grease*, *hand*, *head*, *I*, *leaf*, *leg*, *live*, *louse (head)*, *moon*, *nose*, *raw*, *sesame*, *shoulder*, *this*, *tooth*, *water*, and *you*.

From this evidence, Ostapirat concluded, "It does not seem likely that the very high number of roots between Kra-Dai and Austronesian that emerge from the core list could be accidental or simply result from borrowings." In commenting on Thurgood's claims that there are no regular sound correspondences between the Kra-Dai and Austronesian families, Ostapirat explained that they are the result of Thurgood's being unaware of crucial data from little-known languages, and of the inadequacy of some of his Proto-Kra-Dai reconstructions. Despite the apparent strength of the evidence he cited, Ostapirat nevertheless considered the evidence to be debatable as proof of a genetic relationship between the families.

Authorship Attribution: Statistical and Computational Methods

Introduction

Traditional authorship attribution studies attempt to identify the author of an anonymous text by external methods (e.g., a publisher's payment records, ads in contemporary newspapers) or a subset of available internal methods (e.g., an author mentioning other books that he or she has written, an author mentioning a spouse, or even a practitioner invoking impressionistic stylistic evidence). If a rigorous traditional study of an anonymous work is inconclusive, it should be determined whether a valid nontraditional study could be employed. Nontraditional authorship attribution studies (a.k.a., 'stylometry' or 'stylometrics') use the computer, statistics, and stylistics to arrive at a statement of probability that a suspected author wrote the anonymous work. The nontraditional approach is based on the hypothesis that every writer has a unique and verifiable style. It is important to realize that every nontraditional authorship study is different and demands a unique experimental setup.

Background

When – a Short History

Much of the following brief history is based on the Delcourt (1994) article and other items in the bibliography – specific references can be had there. The quantitative description of texts goes at least as far back as about 300 B.C. Saunaka, a Sanskrit grammarian, counted the number of syllables, words, and stanzas in the *Rig-Veda*. This was done to aid in the accurate preservation of the text. In about 180 B.C., Aristarchus of Samothrace listed 'seldom used expressions' and 'once used expressions' in the *Iliad, Odyssey,* and other Greek works. Aaron Ben-Asher, in about 950 A.D., counted the number of letters, words, verses, and other, even more arcane style markers in the Hebrew Bible.

Many similar studies were done down through the ages. Then, in 1851, Augustus de Morgan stated that word length might prove to be a unique marker of an author's style. This is generally accepted as the beginning of nontraditional authorship attribution studies. T. C. Mendenhall, in 1887, using word-length distributions, conducted the first nontraditional experiment to determine whether it was Bacon or Shakespeare who wrote some disputed plays. There was then a modest spate of activity. Lucius Sherman (1888) worked on sentence length and punctuation as authorship discriminators. Also in 1888, William B. Smith (writing under the name of Conrad Mascol) worked on various style markers in attribution studies. G. W. Gerwig (1894) worked on sentence-length markers in authorship studies. Wincenty Lutoslawski (1897) wrote about a "science of style" that would not only help with chronology problems, but also with "questions of authenticity." Robert E. Moritz (1903) worked on various style markers in attribution studies. In Britain and Germany, classicists also began the quantitative analysis of texts in the 19th century.

The early 20th century saw Andrej A. Markov (1913) studying grapheme sequences, and Godfrey H. Thomson and J. Ridley Thompson (1915) analyzing vocabulary. In 1932, George K. Zipf published the first of his important works. But it was not until the late 1940s that the first large burst of activity started and continued to the 1970s. To name a few of these practitioners, there was George Yule, Gustav Herdan, and C. B. Williams in the United Kingdom; Pierre Guiraud in France; Louis T. Milic, Frederick Mosteller, and David L. Wallace in the United States; Wilhelm Fucks in Germany; Alvar Ellegård in Sweden; and Herman Somers in Belgium. Then in the 1970s, with the increased availability of computers, the number of studies took a quantum leap. Some of these studies appear in the bibliography – but keep in mind that over 1000 other publications do not.

What and Why

Nontraditional authorship studies are interdisciplinary both in their own domain (the computer, statistics, and stylistics) and in 'subject' matter (the data). The subject matter is drawn from many disciplines and can be divided into two groups: group one, where the results are important but not really critical – e.g., literature (in the broadest sense), political science, and history; and group two, where the results are not only important but potentially critical – e.g., religion, the law (both law enforcement and the courts), and the intelligence community.

The reason for doing an authorship attribution study and the ramifications of the subsequent answer are quite different for the two groups. The usual reason for doing an attribution study on group one is to determine an author's canon, so that studies of the author's ideas, stylistic traits, literary techniques, and 'place' in the discipline can be carried out. Each definitive attribution study allows scholars to be more precise and give valid, more meaningful insights

into the history of ideas. Group two, on the other hand, presents more serious implications. What ramifications are presented to Christians in general if the Pauline Epistles were not all written by St Paul? What ramifications are presented to the Church of Jesus Christ of Latter-day Saints if Joseph Smith is shown to be the author of the Book of Mormon? Attribution in the court room can be a matter of a guilty or not-guilty verdict, prison or freedom, even life or death. The FBI uses nontraditional authorship techniques to aid in their investigations – e.g., the writings in the Unabomber case and the note in the Jon Benet Ramsey case. The Rand Corporation is using these techniques to aid the intelligence community in their work on counterterrorism.

Who

Nontraditional attribution studies demand much of the practitioners. Ideally, they must be scholars in the field of the anonymous text – not just in the language, genre, and historical period, but also in the techniques of the editors and publishers. And they must be able to carry out a valid traditional attribution study. They must be competent bibliographers, more than competent statisticians, and competent computer users with a knowledge of programming. They must be 'scientists,' versed in the scientific method, able to construct and implement a valid experimental design.

In reality, very few practitioners meet these criteria. Published practitioners range from undergraduates to scholars of religion, history, literature, philosophy, economics, linguistics, mathematics, statistics, and computer science, and even to physicists, biologists, librarians, and businessmen.

Many studies are done in collaboration. Yet, even in collaboration, not only should all of the areas of expertise be covered, but also every member of the collaboration should have a good enough working knowledge of every other area, so that meaningful checks and balances can be employed. Enough time and resources must be made available to do a valid study. Shortcuts demanded by unrealistic time constraints and money constraints have relegated many published studies to the all-too-large stack of 'highly questionable' works. Too many reviewers are ineffectual gatekeepers, foisting invalid nontraditional studies on an unsuspecting audience and casting doubt on the nontraditional enterprise as a whole.

Where

It is vitally important that attribution researchers be aware of the studies that have gone before. Too many studies cover the same ground, make the same mistakes, and render themselves meaningless because they are unaware of the problems that have been solved and the pitfalls to be avoided. Doing the required bibliographic search is a daunting task, more so than in any other discipline. There are hundreds of different journals in a multitude of disciplines that have published articles on nontraditional authorship attribution. In addition, there are even more journals in more disciplines that have published pertinent peripheral articles on style, stylistics, rhetoric, linguistics, statistics, computational methods, and bibliographic studies – and this is not an exhaustive list. And, although this entry is emphasizing works that were published in English, the practitioner must be aware of and knowledgeable about the wealth of excellent studies written in French, German, Italian, Russian, Japanese, and many other languages.

Dissertations (doctoral, masters, and even undergraduate) offer a rich source of background material and innovative techniques. It is not enough to research only the books about nontraditional studies, but the practitioner should become aware of the dozens of imbedded chapters and sections in books whose titles give no indication of any nontraditional attribution content. And, as in most disciplines, conference papers give the most up-to-date information and allow for valuable give and take.

Methodology

Since there are separate articles in this encyclopedia for corpus linguistics and forensic linguistics (*see* **Corpus Linguistics**; **Applied Forensic Linguistics**) this article concentrates on literary attribution that compares an unknown writing to a suspect author and to all of the other valid potential authors. The use of corpus linguistics in authorship attribution usually compares the unknown writing with a suspect author by using the linguistic norms of a given population. Forensic linguistics usually does likewise, looking especially for linguistic anomalies that are then shown to differ from not only linguistic norms but from the usage by the other suspects in the case. However, any practitioner working in any of these areas must be aware of the methodology used by the others – there is substantial and valuable overlap.

The computer has become so ubiquitous that its use in all of the stages of nontraditional attribution, from bibliographic research and editing, formatting, and analysis of the study texts to formatting and publishing of the final report, is a 'given' and not reported on here. Be forewarned, however, that the technological advances associated with the computer are so rapid and far reaching that the practitioner must continually upgrade his or her skills.

Before any nontraditional attribution study is undertaken, an exhaustive traditional study must be

done. The nontraditional methodology is only a tool for the traditional scholar – and surely not the most important one.

There are four basic categories of nontraditional authorship attribution studies:

1. An anonymous text with no idea of who the author is;
2. An anonymous text with two, three, or some other small number of suspected authors;
3. An anonymous text that is the result of a collaboration;
4. An anonymous text with one suspected author.

In addition to this fractionating, there are almost as many methodological variations as there are studies.

Not all four types of study are treated here. The following is a simplified outline of an ideal experimental design for a category-four study that embraces many techniques. It gives a general idea of what should take place in nontraditional attribution studies. There is much more involved in a valid attribution study. Not all of these steps are necessary for every study – remember, every attribution study is different. Because the field is so complicated, the following concentrates on literary prose. More specifically, an actual authorship problem: Did Daniel Defoe write the anonymous 1705 political tract, *A letter from Scotland to a friend in London* (*Letter*)?

Get the Texts

All necessary texts must be identified and obtained. As a rule, the printed edition closest to the final holograph is to be used; every subsequent edition has the potential to compound the systematic error by allowing editorial and typographical interpolations and errors. The following two are the most important of several criteria to be used in selecting the texts:

1. All of the texts must be the same genre as the anonymous text. In our example, all of the texts must be political tracts. It has been shown empirically that an author uses a different style for different genres. Studies can be done, for example, to see if an author's style in political tracts is statistically the same in closely allied genres, such as religious or historical tracts. This has the potential to increase the size of the data, thereby improving the statistical probabilities.
2. All of the texts must have been originally published in the same constricted time frame, e.g., plus or minus five years. It has been shown empirically that an author's style changes over time. A few of the other criteria are length, gender, and same 'native' language – in our example British English.

These selected texts are divided into three categories:

1. The anonymous text – the *Letter*;
2. The suspected author's texts – every political tract written by Defoe between 1700 and 1710. A random sample of these texts are taken from this sample and used as a control;
3. The control texts – (a) a subset of the suspected author's texts, i.e., the random sample just mentioned above, and (b) a significant random sample of all of the other potential authors of political tracts published between 1700 and 1710.

The ideal would be to include every text that passes the criteria. It is a daunting task for even an expert in 18th century bibliography to identify, locate, and obtain these texts. However, every text that is excluded, for any reason, increases the systematic error of the study.

Each text is then prepared for analysis by unediting, deediting, and editing, e.g., deleting editorial intervention, fixing obvious typesetting errors, deleting quotes, deleting foreign languages, disambiguating (e.g., homonyms), 'marking-up' the text (i.e., tagging the text using a system such as that of the Text Encoding Initiative), and in certain circumstances, lemmatization (see Rudman, 2005). This is an especially vexing problem working with Defoe and 18th century literature – self-quoting, 'imitation,' and plagiarism were the rule rather than the exception. This is a tedious and time-consuming task; well over a million words must be looked at with critical, scholarly care. All texts not already in a machine-readable form are then scanned into the computer by an optical character reader, obtained from the Web, or typed into the computer. Scanning the texts for our example is impractical. The latest 'error rate' obtained in scanning pre ~1750 texts is over 65%. Obtaining texts via the Internet causes other problems, e.g., bad editions and incomplete texts.

Style and Stylistics

Style and stylistics are separate entries in this encyclopedia and it is necessary that the reader of this article be familiar with their content (*see* **Style; Stylistics**). A complete and accurate knowledge of style and stylistics is such a vital part of nontraditional attribution studies that it is with some trepidation that I do no more than point to these entries. As a general rule, practitioners of nontraditional authorship attribution use this operational definition of style: the combination of selected quantifiable stylemarkers. There are

two basic types of these stylemarkers: (1) those that are taken from the author's own words, e.g., word-length distributions, type/token ratios, and percentages of various function words; and (2) stylemarkers that are not the author's own words, e.g., quotations, foreign phrases. Since the use of type-two stylemarkers entails a different kind of study, only type-one markers are referenced in this entry.

Another hypothesis of nontraditional attribution studies is that authors have a conscious control over some stylemarkers while other markers are used unconsciously. Most practitioners feel that the unconscious stylemarkers (e.g., word-length correlation) give more reliable results.

There are hundreds of thousands of quantifiable type-one stylemarkers that have been identified. They can be divided into four main categories: (1) metaword – paragraph (e.g., length, first word of, number of sentences per), sentence (e.g., length, word order, types), phrases, clauses; (2) word – type/token ratios, length distribution, length correlation, once-used words, cooccurrences, function words, parts of speech (e.g., distribution, ratio); (3) subword – *n*-grams, syllables, prefixes, suffixes, phonemes, morphemes, letters; and (4) other – punctuation, imagery, rhetorical devices (e.g., zeugma, chiasmus).

In order to show that a suspected author wrote the anonymous text, it must be shown that the chosen stylemarkers are used in a consistent way by the suspected author, and not used in the same way by the 'other suspected authors' of the control group. Then it also must be shown that the anonymous work uses the same stylemarkers consistent with the suspect author. The determination of which stylemarkers to use is complex; in general, the more markers that pass the selection criteria and are used, the 'better' (higher probability) the answer. Putting this into the context of our example of the *Letter*, we now want to identify those stylemarkers that Defoe uses consistently in his selected writings (minus the randomly selected subset that is to be used as a control).

Sampling

Sampling is used in two different ways in nontraditional attribution studies. One has to do with the intratext block size to be used in determining the variation of a stylemarker within a text. This block size is determined by the stylemarker that is being used, which statistical test is being used, and the length of the text. Given today's technology, the entire prepared text should be used. No block of text should be excluded, even by random sampling. The second way that sampling comes into play is in the selection of the subset of the suspected author's texts and in the selection of 'all other possible authors' control texts. Sampling is not desirable in selecting these texts but is, at times, necessary. It is very rare, if ever, that all of the suspected author's texts (in the same genre and constricted time frame) cannot be used. And, although a random sample of 'all other authors' texts may be necessary, the ideal study would include every text (same genre and constrained time frame) by every author – the closer the sample comes to 100 percent of these authors, the 'better' the results.

Statistics

Much of the following is based on the Holmes (1985) article and other items in the bibliography. The statistics employed in nontraditional studies run the gamut from simple word counts and percentages, through chi-square tests to multivariate analysis and the use of 'learning' programs. These include, for example, neural networks (that recognize the underlying organization of data – a connectionist approach), genetic algorithms (that 'learn' by generating a large number of syntactically valid but semantically meaningless rules), and support-vector machines (that use an optimally defined surface that is typically nonlinear in the input space, linear in a higher-dimensional space, and used for classification, regression and data fitting, and supervised and unsupervised learning). Every practitioner who is not a statistician must possess a level of statistical sophistication that would enable him to at least carry on an intelligent two-way conversation with a statistician. Although the value of the study does not go up with the sophistication of the statistics, very simple statistics usually produce simplistic answers. It is incumbent upon the statistician to understand, employ, and communicate the assumptions behind each statistical test to be used. A statistical technique that requires random input data cannot use stylemarkers that were not produced randomly. A test that requires multiple stylemarkers to be independent cannot produce valid results if the stylemarkers are not independent.

It is usually easier for a practitioner who is a statistician to achieve an adequate level of expertise in stylistics and bibliographical studies than for an expert in literature, history, or religion to achieve a comparable level in statistics. The Mosteller and Wallace (1964) nontraditional authorship study of the *Federalist* papers (arguably the best nontraditional study to date) tried various classical methodologies but made a case for the Bayesian approach. This technique had the added advantage of being able to use the 'best guesses' of traditional authorship practitioners as to who is the author of an anonymous text as the prior-odds input. Their statistically sophisticated study was

the most praised and most cited nontraditional study. However, no practitioner has duplicated his or her methodology on a different authorship problem. This article cannot begin to explicate the mathematical complexity of the statistics that can be used in nontraditional authorship studies. There were many books and articles like Brainerd's (1974) that attempted to do this.

The following is a simplified list of some of the techniques that have been employed in the field: (1) chi-square test, (2) frequency distributions (e.g., percentages, occurrences per block), (3) ratios (e.g., type/token), (4) Simpson's index (*D*), (5) Yule's Characteristic (*K*), (6) Waring-Herdan law, (7) Dolphin-Muller law, (8) Zipf's law, (9) Ule's relative vocabulary overlap, (10) Morton's Qsum, (11) Burrows's Delta, (12) *z*-test, (13) *t*-test (for independent samples), (14) *t* test (for correlated samples), (15) *f*-test (e.g., analysis of variance [anova]), (16) Markov chains, (17) phi coefficient, (18) Spearman rank correlation coefficient, (19) Kendall rank correlation, (20) Pearson product moment correlation, (21) entropy, (22) Mann-Whitney *U* test, (23) Wilcoxon test, (24) factor analysis, (25) discriminant analysis, and (26) cluster analysis. Many variations of these tests also have been employed.

Very few of these techniques have escaped criticism from other statisticians. There are no universally accepted statistical methodologies in nontraditional authorship attribution. The use of multivariate methodologies seems to show a consensus of acceptability and preferability by present day practitioners.

The use of 'packaged' statistical programs poses dangers to the unsuspecting nonstatisticians. It is not always clear exactly what algorithms are used in the 'black box' or what assumptions are made about the data. When all of the statistical manipulation is finished, a complete and completely understandable presentation of the results should be made. A picture (or graph) is worth much more than 1000 tables of numbers. A statement of probabilities has to be accompanied by a meaning of the statistical probabilities.

Returning to the *Letter* example with all of this in mind, the practitioner now wants to identify those stylemarkers that Defoe uses consistently in his primary sample of selected writings. This is done by testing the thousands of potential stylemarkers on the primary Defoe data. Say, for illustrative purposes, that Defoe uses 500 stylemarkers in a consistent way throughout his selected writings, e.g., every 1000 word block shows, within acceptable statistical error, the same word-length distribution, the same type/token ratio, the same various function-word distributions. These 500 markers are then tested against the 'all other potential authors' control sample. This is done to weed out those markers that are zeitgeist-driven or genre-driven. Again, for illustrative purposes, say that 200 of these 500 stylemarkers are genre- or zeitgeist-driven, i.e., the control group uses these 200 markers in the same way (statistically) that Defoe does. These 200 markers are discarded from further study.

This is not to say that any of the remaining 300 stylemarkers are not used by any of the control group authors in the same way as Defoe, but that none of the other authors use all of these markers the same way (statistically) as Defoe – an important distinction. The amount of this overlap correlates with the probability of the answer. The next step is to test the remaining 300 stylemarkers against the *Letter*. Does the author of the *Letter* show the same statistical stylemarker usage as Defoe? But before going to an 'answer,' the Defoe subgroup control that was randomly selected before analysis began is tested to ensure that there was no 'cherry picking' of stylemarkers (even unconsciously) by the practitioner. If the subsample control exhibits the same statistical results as the main Defoe sample with all 500 stylemarkers, the marker selection is validated. Now, only the final probability (with experimental and systematic error rates) remains to be calculated.

Keep in mind that this example of the *Letter* is the most difficult type of authorship problem. If there are only a few possible candidates for authorship, as in the *Federalist* dispute, the 'other potential author' control group becomes more manageable and allows for a 'more reliable' answer but to a different and far easier problem: which of the limited number of potential authors is the most likely to have written the text.

Conclusion

Nontraditional practitioners (and many others) look upon their work as 'science,' with the concomitant commitment to produce and follow a complete and valid experimental design. However, there are many skeptics who look at the field as pseudoscience or simply 'aspiration' to become a science. The skepticism (not entirely unjustified) is the result of many factors, besides the ones mentioned earlier: (1) a lack of consensus on methodologies, techniques, and results; (2) many (if not most) practitioners allow their work to be governed by expediency – it is easier to take shortcuts than do a 'complete' experiment; (3) a lack of expertise in all of the allied fields; and (4) a lack of understanding of what is required and what has been done in the field. In addition to these there are the well-publicized 'mistakes' (e.g., the debunking

of Morton's Qsum methodology by England's Channel 4 program 'Street-legal,' and the much ballyhooed Foster attribution of the *Funerall elegye* to Shakespeare, with the subsequent proof that he was in error – an error that Foster admitted in a retraction.

If the experimental design has any flaws, the entire study is put in doubt. This is truly a case where the chain is only as strong as its weakest link. Yet even these flawed outcomes must be studied by practitioners. And, if a practitioner publishes a flawed study, it does not mean that all of his or her studies are flawed; *Erratum in unum* does not mean *erratum in omnes*. There are two important principles that the practitioner must follow: (1) completeness – every detail must be published or made available; and (2) reproducibility – any other competent practitioner must be able to reproduce the results.

Nontraditional attribution studies do not give a 'yes' or 'no' answer. Answers are expressed in statistical probabilities. This is not to denigrate the value of these answers; the probabilities can approach certainty the same way that DNA analysis does. The answer can be presented to the 'jury' as being beyond a reasonable doubt.

The future full acceptance of nontraditional authorship studies as a legitimate discipline does not lie with more-sophisticated statistical techniques; the successful implementation of a neural net or support vector machine cannot make up for faulty control selection or faulty primary text preparation. Its future lies with a rigorous adherence to valid experimental designs.

Because of length restrictions, this article cannot do the subject justice. I have tried to give the curious reader and the serious researcher a good idea of what nontraditional authorship attribution is all about and how a fledgling practitioner might get started.

Bibliography

[Note: There are well over 100 different journals that publish articles pertaining to nontraditional authorship attribution. The following two journals are worth noting for the quantity and quality of these articles: *Literary and Linguistic Computing* and *Computers and the Humanities*. The following 30 entries were selected from a bibliography of well over 1000 items. They were selected for their representativeness, importance, and/or historical value to the field. This bibliography does not contain the seminal and other important works in style and stylistics by such giants as Yule, Milic, and Burrows or in other component fields such as forensic linguistics by practitioners like McMenamin and Chaski.

Autism and Asperger Syndrome: A Spectrum of Disability

H Cohen and S Rémillard, Université du Québec à Montréal, Montréal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Autism spectrum disorder (ASD) is a severe developmental disorder, first labeled and described by Kanner in 1943. The onset of ASD occurs before age 3 and persists throughout life. A male predisposition exists with a ratio of approximately 3 to 1. The prevalence of this disorder is approximately 1 of every 1000 births. According to the *Diagnostic and statistical manual*, 4th edition (DSM-IV; American Psychological Association), and the *International classification of diseases*, 10th edition (ICD-10; World Health Organization), this disorder is part of the Pervasive Developmental Disorders category and is characterized by three main disabilities: (1) failure to develop normal social interactions and relationships, (2) language delay and communication disability, and (3) restricted, repetitive, and stereotyped behaviors. Mental retardation is frequently associated with autism. Approximately 75% of individuals with autism have severe mental retardation (also known as low-functioning autism; LFA), and the rest have mild retardation or average intelligence (also called high-functioning autism; HFA). Approximately 10% of individuals with ASD may have very low levels of intellectual abilities, but show excellent rote memory and possess isolated savant skills, such as calendar calculations, exceptional musical or drawing abilities (Volkmar and Pauls, 2003).

Individual differences in ASD are also observed in language development. Some children with autism never develop speech, whereas others become verbally fluent but still have problems with comprehension and language use. As the manifestation of autism varies in degree of severity and from one individual to another, it is generally assumed that there is a spectrum of autistic disabilities ranging from LFA to HFA and Asperger's syndrome (AS). The distinction between LFA and HFA consists mainly of the fluency and flexibility of expressive language skills (Lord and Paul, 1997). LFA individuals may be mute or may acquire only minimum speech characterized by echolalia (the immediate repetition of what is said by another person) without any apparent communication purpose. HFA individuals develop speech, but tend to show idiosyncratic use of words and phrases and have difficulty participating in conversation (Bushwick, 2001). Asperger's syndrome constitutes a milder variant of the autism spectrum and, like the autistic disorder, is characterized by social disability and restricted stereotyped behaviors. However, AS individuals do not show mental retardation and language acquisition delay as in autism (Volkmar and Klin, 2000). Consequently, AS is often not diagnosed until late childhood or even adulthood. The prevalence of AS is higher than that of autism and is estimated at 3 of 1000 births. Although the cause of ASD is unknown, there is strong evidence for a genetic contribution to the development of the disorder. The concordance rate for monozygotic twins is very high (i.e., over 90%; Volkmar and Pauls, 2003).

Autism and Asperger Syndrome: A Spectrum of Disability

H Cohen and S Rémillard, Université du Québec à Montréal, Montréal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Autism spectrum disorder (ASD) is a severe developmental disorder, first labeled and described by Kanner in 1943. The onset of ASD occurs before age 3 and persists throughout life. A male predisposition exists with a ratio of approximately 3 to 1. The prevalence of this disorder is approximately 1 of every 1000 births. According to the *Diagnostic and statistical manual*, 4th edition (DSM-IV; American Psychological Association), and the *International classification of diseases*, 10th edition (ICD-10; World Health Organization), this disorder is part of the Pervasive Developmental Disorders category and is characterized by three main disabilities: (1) failure to develop normal social interactions and relationships, (2) language delay and communication disability, and (3) restricted, repetitive, and stereotyped behaviors. Mental retardation is frequently associated with autism. Approximately 75% of individuals with autism have severe mental retardation (also known as low-functioning autism; LFA), and the rest have mild retardation or average intelligence (also called high-functioning autism; HFA). Approximately 10% of individuals with ASD may have very low levels of intellectual abilities, but show excellent rote memory and possess isolated savant skills, such as calendar calculations, exceptional musical or drawing abilities (Volkmar and Pauls, 2003).

Individual differences in ASD are also observed in language development. Some children with autism never develop speech, whereas others become verbally fluent but still have problems with comprehension and language use. As the manifestation of autism varies in degree of severity and from one individual to another, it is generally assumed that there is a spectrum of autistic disabilities ranging from LFA to HFA and Asperger's syndrome (AS). The distinction between LFA and HFA consists mainly of the fluency and flexibility of expressive language skills (Lord and Paul, 1997). LFA individuals may be mute or may acquire only minimum speech characterized by echolalia (the immediate repetition of what is said by another person) without any apparent communication purpose. HFA individuals develop speech, but tend to show idiosyncratic use of words and phrases and have difficulty participating in conversation (Bushwick, 2001). Asperger's syndrome constitutes a milder variant of the autism spectrum and, like the autistic disorder, is characterized by social disability and restricted stereotyped behaviors. However, AS individuals do not show mental retardation and language acquisition delay as in autism (Volkmar and Klin, 2000). Consequently, AS is often not diagnosed until late childhood or even adulthood. The prevalence of AS is higher than that of autism and is estimated at 3 of 1000 births. Although the cause of ASD is unknown, there is strong evidence for a genetic contribution to the development of the disorder. The concordance rate for monozygotic twins is very high (i.e., over 90%; Volkmar and Pauls, 2003).

Neuroanatomic and neuroimaging investigations have revealed functional and structural brain abnormalities in individuals with ASD, such as hyperserotonemia, reduced volume of cerebellar vermis, and abnormalities in cell structure in the hippocampus and amygdala (Beauman and Kemper, 2003). High rates of seizures have also been observed in individuals with ASD. The similarity of autistic impairments with frontal lobe and right hemisphere lesions (Martin and McDonald, 2003) and Landau–Kleffner syndrome (*see* **Landau-Klefner Syndrome**) (Levisohn, 2004) has been highlighted.

Abnormal auditory cortical processing of complex sounds in children with autism has also been revealed in a positron–emission tomography activation study and confirmed previous results obtained in adults. This irregular processing seen in both adults and children with autism could be involved in inadequate behavioral responses to sounds and in language impairments characteristic of autism (Boddaert *et al.*, 2004). In addition, a language-association cortex asymmetry was revealed in autism and specific language impairment (SLI), suggesting a phenotypic link between autism with language impairment and SLI. Language-impaired boys with both autism and SLI had reversal of asymmetry on frontal language-related cortex, whereas linguistically unimpaired ASD boys had asymmetry similar to that found in the control group. It would appear that this asymmetry reversal is more a reflection of language impairment than specifically linked to autism diagnosis (De Fosse *et al.*, 2004).

Language in ASD and Asperger's Syndrome

As most autistic children are usually diagnosed around 3 or 4 years of age, few investigations have been conducted with younger children. However, retrospective analyses of home videotapes of 1 year old children later diagnosed with ASD and parental reports of their child's language have provided useful information about the preverbal phase of the autistic disorder. Lord *et al.* (2004) reported that parents often observe word loss in the second year of life in children with autism. In addition, 1 year old autistic children are less responsive to their names or attend less to people than do typically developing children. The autistic child's failure to orient preferentially to speech, share attention, and use eye gaze to disambiguate an adult's intention may be the earliest signs of the disorder and constitute particularly strong handicaps for the acquisition of language (Dawson *et al.*, 2004; Rollins and Snow, 1998).

Language impairment is an important part of the diagnostic in autistic spectrum disorders. As already mentioned, many children with autism may never learn to speak or show any attempt to communicate through compensating gestures or body expressions. Those children who acquire speech, approximately 50% of autistic individuals (Minshew *et al.*, 1992), show striking peculiarities such as unusual intonation, severe difficulties in social use of language (pragmatics), echolalia, neologisms, and pronominal reversal (e.g., using 'you' instead of 'I').

Comprehension of language is often more delayed than expression in individuals with autism. As reported by Bartak *et al.* (1977), children with autism show more severe deficits in speech comprehension when compared to other mentally retarded children, matched for nonverbal cognitive level, as well as to normally developing children (Tager-Flusberg, 1981). More recently, a study of 134 children with autism, without severe mental retardation, showed that word comprehension and sentence comprehension were more delayed than word production, in contrast with the performance of the normative sample as measured by the MacArthur Communicative Development Inventory (Charman *et al.*, 2003).

The phonological processing of 80 probands with ASD and 59 healthy controls was thoroughly assessed by Bishop *et al.* (2004). In that study, the parents of the participants completed a battery of tests including verbal and performance IQ, nonword repetition, nonsense passage reading, and a questionnaire about history of language and literacy problems. Interestingly, verbal IQ was the only measure to show any familiality within the index group. It appears that phonological processing impairments are not part of the ASD phenotype.

Pragmatic Language

Most individuals with a diagnosis of HFA and AS eventually develop good verbal skills (although delayed in HFA), with the ability to engage in relatively fluent and articulate speech, but still show marked deficits in pragmatic language abilities (i.e., the appropriate use of language in social context; Happé, 1993; Martin and McDonald, 2003). The language of individuals with AS is often described as pedantic, tangential, and overtalkative. These individuals also tend to have an overliteral understanding of what is said. In addition, individuals with AS have difficulty with the pragmatic interpretation of nonliteral utterances, such as metaphors, irony, and narrative humor (Happé, 1993; Martin and McDonald, 2003).

The ability to repair communicative breakdown is an important pragmatic skill. A number of studies have consistently shown that individuals with ASD generally recognize communicative breakdown and adequately respond to requests for clarifications (RQCL) with a variety of repair strategies. However, Volden (2004) has shown that children with ASD were more likely than language age-matched peers to respond to an RQCL with an inappropriate response.

Prosody

Segmental or articulatory aspects of speech have been reported to be generally appropriate for the developmental levels of people with HFA or AS (Bishop, 2003; Tager-Flusberg, 1981). However, abnormal suprasegmental aspects of speech, or prosody, constitute another characteristic frequently observed in autism (McCaleb and Prizant, 1985; McCann and Peppé, 2003; Rutherford *et al.*, 2002; Tager-Flusberg, 1981). Therefore, abnormal tone, pitch, and modulation of speech are common. Specifically, studies on the use of contrastive stress (a component of prosody used to highlight an important word in an utterance, as the focus of attention) showed that individuals with autism tend to use stress in an atypical way (McCaleb and Prizant, 1985). Children with autism misassigned stress twice as often as typically developing children. However, as contrastive stress is dependent on the pragmatic intention of the speaker, a deficit in that aspect of prosody may be in fact a pragmatic deficit. In addition, Rutherford *et al.* (2002) investigated the affective aspects of prosody. They asked participants to listen to 40 stimuli and then decide which of two adjectives best described the affective content of the stimuli. Their results suggest an impairment in the comprehension of prosodic affect in individuals with HFA and AS.

Verbal Semantic Processing

According to Charman *et al.* (2003), children with autism have a broadly similar pattern of acquisition of different word categories and types than typically developing children. Lopez and Leekam (2003) reported no difficulty in a word-priming task as HFA and typically developing children showed similar facilitation effects. They all identified words related to a prime faster than words preceded by a neutral prime.

The fact remains that specific difficulties in semantic aspects of language have been reported in individuals with autism. The observed impairments refer to the understanding of particular types of words (i.e., terms with social or emotional content). As measured by the British Picture Vocabulary Scale, individuals with autism showed specific difficulties in understanding emotion-related terms, but not with emotion-unrelated ones (Hobson and Lee, 1989). Other studies have reported a specific impairment with terms having deictic function (terms that change their meaning according to the context in which they are used, e.g., 'you,' 'now,' 'there,' 'this'; Charman *et al.*, 2003). Individuals with HFA also showed impairment in processing lexical ambiguous sentences (Jolliffe and Baron-Cohen, 1999) and interpretation of homographs (Happé, 1997); both tests involve the ability to adequately interpret the context in order to understand the meaning of the sentences.

Syntactic Aspect of Language

Syntactic development has not been well studied in autism. There is considerable individual variation in grammatical skill among children with autism. Many children never acquire productive syntax, but others show relatively high achievement (Rollins and Snow, 1998). Generally, in fluent HFA, sentences are grammatically intact. Dawson *et al.* (2004) and Rollins and Snow (1998) have shown that the establishment and manipulation of joint attention (the ability to coordinate attention between another person and an object or event of interest) may be a pragmatic skill prerequisite to the development of productive syntax. Their observations showed a strong association between pragmatic and morphosyntactic skills with autistic children who rarely established a joint focus of attention (Rollins and Snow, 1998).

Theoretical Understanding of Autism

Three hypotheses have been suggested to explain the cognitive and social features of autism. The first and most prominent position on the causation of social impairment in autistic disorder is the theory of mind hypothesis (ToM; i.e., a deficit in mental inference ability). This model suggests that an inability to attribute mental states to others (i.e., intentions, desires, feelings, and beliefs) leads to difficulties in effective communication and therefore in social interactions (Volkmar and Pauls, 2003). The ToM hypothesis has been widely studied using the standard False Belief Task (Martin and McDonald, 2003). Children with autism characteristically fail this test (Happé, 1993). In addition, Happé (1993) observed a strong association between ToM deficits and pragmatic comprehension in autism. The level of ToM complexity

(first- or second-order intentions) is related to the ability to understand similes (a literal level of comprehension), metaphors (first-order intention), or irony (second-order intention). However, Ozonoff *et al.* (1991) found that adolescents diagnosed with AS do not fail ToM tasks as children with autism do, suggesting that they possess an understanding of mental states. However, AS children still have major difficulties with social interactions. Despite strong evidence of an association between ToM deficits and communication difficulties in autism, this model is somewhat limited in the explanation of their impaired social interactions.

A second hypothesis, the weak central coherence hypothesis (WCC), was proposed by Frith (1989) to explain the tendencies of people with autism to pay preferential attention to parts rather than global coherent patterns of information. This hypothesis takes into account their pragmatic deficit – an impairment in the ability to use language appropriately in context – and also their superior capacities of recalling and processing information. Because this theory suggests that autistic individuals pay preferential attention to segments rather than whole features of objects, it can explain the superior performance of autistic individuals over normal healthy controls, as on the Block Design subtest of the Wechsler Adult Intelligence Scale (WAIS), for example. However, some authors have found that global processing was intact in individuals with autism (e.g., Ropar and Mitchell, 2001). Thus, the WCC remains a controversial hypothesis.

The impaired executive functions hypothesis in autism is a third explanatory perspective of a primarily social impairment. Executive functions underlie planning, social judgment, insight, inhibition, flexibility, and working memory mediated by the frontal lobes. Consequently, the obsessive desire for sameness, restricted interests, and stereotyped and rigid behaviors that characterize individuals with autism have been associated with a deficit in executive function skills, which may explain their poor social skills. In order to assess executive dysfunction in autism, Ozonoff and McEvoy (1994) used the Wisconsin Card Sorting Test (WCST) and the Tower of Hanoi Test. In contrast to typically developing controls, children with autism showed a poor performance on both of these executive function tests. Nevertheless, executive function deficits are not specific to autism and a more recent study showed that there exists an association between performance on the WCST and social impairment in autism, but no relationship with communication impairment (Liss *et al.*, 2001).

Treatment and Prognosis

Autism spectrum disorder is a lifelong disability. Although the symptoms may improve with age, most individuals with ASD or AS still show impairments in social and occupational functioning later in life. Onset of speech before the age of 5 (Venter *et al.*, 1992) and joint attention abilities (Dawson *et al.*, 2004) have been associated with a good prognosis. To date, there is no recognized medical treatment for the core deficits in autism. However, developmental, behavioral, and educational therapeutic programs have met with some success in helping reduce behavior problems and in fostering communication. Positive effects with significant improvement in language and social behavior have been reported with individual and intensive interventions dispensed early in childhood (Howling, 2003). However, clinical intervention should also focus on utterances that disrupt the conversational flow and that generate severe social penalties for the speaker with ASD (e.g., Volden, 2004).

Autolexical Syntax

J M Sadock, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Though the name implies a syntactic theory, Autolexical Syntax (ALS) is actually a view of the relationship among the various components of a grammar only one of which is syntax. The name is justified, however, because in more mainstream grammatical theories much of what is included in syntax is seen in ALS as the province of other components, particularly morphology and semantics. In ALS distinct grammatical levels are described by autonomous grammars, called modules, each of which generates a set of well-formed representations at a single level.

The foundational article (Sadock, 1985) considered mainly the syntactic and morphological levels, applying the idea of autonomous syntactic and morphological representations to the analysis of two phenomena, cliticization and incorporation. Both were taken to be cases of significant, but allowable, structural discrepancy among independent representations provided by the syntactic and morphological modules. English auxiliary clitics, for example, were analyzed as syntactically identical to their free-verb counterparts, but, at the same time, as suffixes in the parallel morphology. The noun incorporating suffixes of West Greenlandic Inuit, or Kalaallisut (Inuktitut, Greenlandic), were taken to be transitive verbs in the syntax and, at the same time, verb-forming suffixes in the morphology. The position of both clitics and incorporating affixes thus presented mismatches in two autonomous modules, as illustrated in Figures 1 and 2, which are typical of work in the framework. Such diagrams present the structure of expressions in the form of two (or more) simultaneous trees, each one corresponding to an analysis in a single module.

(1) Jones or Smith's leaving.

Figure 1 English Auxiliary Clitic.

(2) Hansi qernertu-mik qimme-qar-poq
Hans black-INSTR/SG dog-have-INDIC/3SG
'Hans has a black dog.'

One requirement for full grammaticality in this model is that an expression must be properly analyzable in each of the modules. In addition, ALS contains an interface component that ensures that various features of the autonomous representations correspond to some degree. Part of the interface includes the lexicon, since all of the representations of an expression must be compatible with the same set of lexical items. (Compare the idea of a numeration in the Minimalist Program.) In order to limit both the degree and kind of mismatches that the system allows, two quite specific interface constraints were suggested in Sadock (1985). Parts of morphological words are ordinarily not represented in the syntax at all, but if they are, the following interface principles were assumed: (1) The Cliticization Principle, which requires that a host word and a morphological clitic be linearly adjacent in syntax, and (2) The Incorporation Principle, which demands that a host stem and an affix or stem with which it combines morphologically be the head of a syntactic phrase and the head of its complement. (Compare head movement in the government and binding framework.) The interface was also charged with the task of adjudicating conflicts between modules. For example, one component may require the order B-A, and another the order A-B. A hierarchy of strength of components was proposed as the major feature of the system of conflict resolution: morphology outranks syntax and syntax outranks semantics. In cases of conflict the higher-ranked module wins out.

Subsequent research turned up a number of phenomena that did not fit the stringent requirements of

Figure 2 West Greenlandic (Inuktitut) Incorporation.

the Cliticization and Incorporation Principles. Hans Smessaert (1996), for example, described the system of West Flemish (Westrlaams) pronominal clitics, which attach to complementizers or to finite verbs, even if the position of the free correspondent of the clitic is quite some distance away, and even if there is an intervening head such as a preposition, as in the following example where the element *-der-* is a clitic in the morphology and the syntactic object of the stranded preposition *mee,* which is two words away from where it would be found as an independent NP:

(3) k-èn-der-ik ol mee èklapt
1sNOM-have- already with talked
PREP.OBJ-1sNOM
'*I have already talked to him/her.*'

Based on such examples, the interface constraints were generalized (and weakened). In their place, Sadock (1991) suggested a Weak and Strong L(inearity) C(onstraint) demanding two different degrees of correspondence in linear order between independent representations, and a Weak and Strong C(onstructional) I(ntegrity) C(onstraint), enforcing two different degrees of match in terms of the hierarchical position of elements found in both the syntax and morphology. The Strong LC is similar to the older Cliticization Constraint and the Strong CIC does much the same job as does the Incorporation Constraint, while the weak versions allow for a lesser degree of correspondence.

Further examples required even further generalization (and weakening) of the interface. In Sadock and Schiller (1993) all constraints on the interface were reduced to a single principle, the Generalized Interface Principle, which requires all structural features of two independent representations of an expression, including linear order, hierarchical position, and also category, to match as closely as the content of the levels and the demands of lexical items allow. While attractive in its generality, this principle does not actually place any absolute limits on discrepancies between modular representations. It does, however, make mismatches costly in terms of the lexical and/or grammatical specifications that would be required to override the default tendency toward full intermodular matching.

Subsequent work made it clear that other levels of organization beyond the classical trio of syntax, semantics, and morphology needed to be recognized. Woodbury (1996) and Chelliah (1996) drew an important distinction between morphology proper and morphophonology; Faarlund (1996) suggested an independent module representing expressions in terms of predicates and thematic roles.

During the 1990s the emphasis of work in ALS shifted from morphology-syntax discrepancies to syntax-semantics discrepancies, covering such topics as control phenomena, complementation, lexical categories, and compounding. More complex analyses that take account of the interaction of three or more components at the same time have also appeared. A number of languages have been addressed from an ALS perspective, including English, French, Japanese, Hungarian, Norwegian, Circassian (Adyghe), Bangla (Bengali), Welsh, Crow, and Hebrew.

Research in the late 1990s and early 2000s has emphasized individual constraints in addition to, or perhaps instead of, the systems of rules that constitute the modules. This work recognizes a number of distinct forces that compete for expression in surface form and therefore resembles Optimality Theory, although in the ALS framework the constraints are weighted rather than ranked and can exhibit additive effects. Intermediate degrees of grammaticality are recognized as cases in which conflicts among forces are unavoidable. The more serious the conflicting demands of the constraints are, the less acceptable the form is predicted to be.

Jackendoff (1997, 2002) has put forward a similar model which shares with the present model the idea of independent modules whose outputs are connected by an interface system, although the details of the various modules themselves differ somewhat from the ordinary practice of those working in ALS. His semantics, for example, are more similar to what is found in Faarlund (1996) than to the predicate-calculus semantics of most other works in ALS.

Autonomy

E Mathieu, University of Ottawa, Ottawa, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

The concept of autonomy is a recurrent topic in linguistics and has been hotly debated, especially with the advent of transformational generative grammar. At least three independent systems have been claimed to be autonomous: syntax, knowledge of language, and grammar. Together, they form the Autonomy Hypothesis, which, following Croft (1995) and Newmeyer (1998), can be formulated as follows:

1. Syntax is self-contained; it has its own primitives and makes no reference to semantic or discourse-related external elements.
2. Knowledge of language or competence is independent of language use or performance.
3. Grammar is a self-contained system that makes no reference to system-external factors.

The innateness hypothesis often associated with generative grammar is independent of the autonomy hypothesis and its three subcomponents. For example, the idea that grammar or language constitutes an autonomous entity (i.e., a module; subhypothesis 3 above) can be adopted within a nativist (Chomsky, 1972, 1975, 1986; Fodor, 1983), constructivist (Karmiloff-Smith, 1992), or behavioral/associationist conception of the mind. Development can thus be seen as involving a gradual process of modularization, through learning in the traditional sense, without necessarily postulating innate structure.

In addition, one can adopt subhypothesis 3 or subhypothesis 1 without necessarily subscribing to the proposal in subhypothesis 2. A case in point is Fodor's (1983) view of language as an input system, which challenges Chomsky's conception of language as both an input and an output system, with the latter clearly distinguishing knowledge of language from its implementation in language processing (see Newmeyer 1998: 25 for discussion).

Concentrating on the autonomy of syntax, Chomsky's point is that a sentence can be ungrammatical yet have meaning: although sentence (1a) is ill-formed in English, the sentence can easily be understood as signifying the same as its grammatical counterpart (1b).

(1a) *John his books sold.
(1b) John sold his books.

Second, a sentence can be grammatical but make very little sense. As a way of illustration, consider Chomsky's (in)famous example in (2):

(2) Colorless green ideas sleep furiously.

This sentence is certainly grammatical. Compare (2) with (3), which contains the same string of words, but in a different order. Native speakers of English converge in rejecting (3) as ungrammatical, whereas they see that in (2) no rule of grammar has been violated (the adjectives appear before the noun, the subject is placed before the verb, etc.).

(3) *Furiously sleep ideas green colorless.

These simple examples are often taken to show that there should be two linguistic levels of representation, one syntactic and the other semantic. The implication that this view has for the pairing between structure and meaning is that there is no one-to-one correspondence between syntax and semantics. Syntax has its own set of principles that are independent from semantics. A case in point is the behavior of weak islands. In the generative literature, the split construction in (4a) is taken to be perfectly interpretable with the reading in (4b) (Rizzi, 1990). Yet the sentence is ill-formed because it violated a syntactic principle, that of locality. The negative element 'pas' (not) is of the same type as 'combien' (how many) and is thus closer to its target (i.e., the left-most position in the sentence) than the interrogative operator.

(4a) Combien as-tu lu de livres?
how-many have-you read of books
'How many books have you read?'
(4b) Which is the number x, x a book, such that you have read x.

Most (if not all) functionalists reject the contention that there is no one-to-one mapping between form and interpretation, preferring a one-to-one mapping,

The concept of autonomy is a recurrent topic in linguistics and has been hotly debated, especially with the advent of transformational generative grammar. At least three independent systems have been claimed to be autonomous: syntax, knowledge of language, and grammar. Together, they form the Autonomy Hypothesis, which, following Croft (1995) and Newmeyer (1998), can be formulated as follows:

1. Syntax is self-contained; it has its own primitives and makes no reference to semantic or discourse-related external elements.
2. Knowledge of language or competence is independent of language use or performance.
3. Grammar is a self-contained system that makes no reference to system-external factors.

The innateness hypothesis often associated with generative grammar is independent of the autonomy hypothesis and its three subcomponents. For example, the idea that grammar or language constitutes an autonomous entity (i.e., a module; subhypothesis 3 above) can be adopted within a nativist (Chomsky, 1972, 1975, 1986; Fodor, 1983), constructivist (Karmiloff-Smith, 1992), or behavioral/associationist conception of the mind. Development can thus be seen as involving a gradual process of modularization, through learning in the traditional sense, without necessarily postulating innate structure.

In addition, one can adopt subhypothesis 3 or subhypothesis 1 without necessarily subscribing to the proposal in subhypothesis 2. A case in point is Fodor's (1983) view of language as an input system, which challenges Chomsky's conception of language as both an input and an output system, with the latter clearly distinguishing knowledge of language from its implementation in language processing (see Newmeyer 1998: 25 for discussion).

Concentrating on the autonomy of syntax, Chomsky's point is that a sentence can be ungrammatical yet have meaning: although sentence (1a) is ill-formed in English, the sentence can easily be understood as signifying the same as its grammatical counterpart (1b).

(1a) *John his books sold.
(1b) John sold his books.

Second, a sentence can be grammatical but make very little sense. As a way of illustration, consider Chomsky's (in)famous example in (2):

(2) Colorless green ideas sleep furiously.

This sentence is certainly grammatical. Compare (2) with (3), which contains the same string of words, but in a different order. Native speakers of English converge in rejecting (3) as ungrammatical, whereas they see that in (2) no rule of grammar has been violated (the adjectives appear before the noun, the subject is placed before the verb, etc.).

(3) *Furiously sleep ideas green colorless.

These simple examples are often taken to show that there should be two linguistic levels of representation, one syntactic and the other semantic. The implication that this view has for the pairing between structure and meaning is that there is no one-to-one correspondence between syntax and semantics. Syntax has its own set of principles that are independent from semantics. A case in point is the behavior of weak islands. In the generative literature, the split construction in (4a) is taken to be perfectly interpretable with the reading in (4b) (Rizzi, 1990). Yet the sentence is ill-formed because it violated a syntactic principle, that of locality. The negative element 'pas' (not) is of the same type as 'combien' (how many) and is thus closer to its target (i.e., the left-most position in the sentence) than the interrogative operator.

(4a) Combien as-tu lu de livres?
how-many have-you read of books
'How many books have you read?'
(4b) Which is the number x, x a book, such that you have read x.

Most (if not all) functionalists reject the contention that there is no one-to-one mapping between form and interpretation, preferring a one-to-one mapping,

and accusing formalists in passing of having a syntax bias. However, it must be noted that the term 'formalist,' although often used by functionalists (sometimes with derogatory force) to describe generativists, is odd in this context. This is because one can be a formalist without subscribing to the two-level hypothesis. Montague's grammar (Montague, 1974), for instance, and the semantic tradition that stems from it, is purely formal, and its practitioners are typical formalists, yet for most such semanticists, there is a direct mapping between syntax and semantics. See Sadock (2003) for ample discussion.

Nevertheless, it must be added that, as perspicaciously mentioned by Newmeyer (1998), the term 'formalist' is ambiguous – it can refer either to 'form' as in syntax (as opposed to meaning) or 'form' as in 'formal*ized*' or 'formaliz*able*.' Quoting Newmeyer (1998: 8): "While functionalists have not produced formalized theories, many agree that in principle there is nothing about their orientation that should prevent them (someday) from doing so" (Li, 1976; Croft, 1995; Bybee, 1998). It is fair to say, however, that many functionalists themselves use the term 'formalist' negatively in both senses of the word.

Although the position of functionalists on form is often greatly exaggerated, the idea that Chomskyan linguistics pays no attention to function is also a caricature. In recent years, Chomsky (1995, 2000, 2001) has put forward the hypothesis that movement phenomena are driven by syntax external factors (including discourse notions among others). However, syntax being a perfect system (in the sense that it is designed to counter external pressures) has at its disposal features that are responsible for displacement. These features are formal features: they must be checked and erased as the derivation proceeds. They are, in other words, the formal encapsulation of function. The autonomy of syntax is therefore as relevant a topic for mainstream generative linguistics as it was 40 years ago.

In recent years, the autonomy of syntax has nonetheless appeared to be under threat within some generative circles. This is perhaps most obvious in the work of Fox (1995, 2000) and Reinhart (1995), in which Quantifier Raising (QR) may only apply to derive a L(ogical) F(orm) with interpretation α if α cannot be derived without that application of QR. In other words, QR applies only if it changes the *in situ* scope relations, allowing a kind of leakage of the semantics into the syntax.

One way to solve the leakage problem (assuming it is a problem) is to postulate a feature as part of the Numeration. This is exactly what Chomsky (1995) does when he suggests that QR involves the raising of a quantificational feature to some functional head (T or v) that is a potential host. The idea is that the host has an optional affix feature allowing it to host. This proposal is in accordance with the basic minimalist requirement that the operation Move is motivated by feature checking. In this view, optionals are built into the lexicon, and there is no sense that the semantics are looking down at the syntax. The operation QR is dependent on the insertion of a feature, and this is a lexical decision before, or at least while, the derivation proceeds.

Less discussed, at least in explicit terms, is the threat to the autonomy of syntax from the so-called cartography approach (at least in its strong form). Following the work of Rizzi (1997) and many others, researchers have argued in recent years that CP (Complementizer Phrase), and perhaps DP (Determiner Phrase), should be split into several distinct positions. This is an empirical domain of research, and it has achieved great results, showing for instance that focus and topic positions should be syntactic positions in their own rights. However some take the view that *a priori*, each semantic or pragmatic function should have a syntactic position. For example, Benincá and Poletto (2004: 1) say that: "One assumption that seems natural to us, and possibly valid even beyond the immediate scope of this article, is that there is a one-to-one relation between position and function." In the same vein, they declare (2004: 1): "There is no limit, in our view, as to how many these projections will ultimately be, provided that there is syntactic and semantic justification for them."

Although it is from a different angle, this line of research resembles that of Diesing (1992), who argues that there is a strict mapping between syntactic position and interpretation (in her view, a presuppositional NP (Noun Phrase) must appear in high IP (Inflectional Phrase)-external position, whereas a nonpresuppositional NP must appear in a low IP-internal position (see also de Hoop [1992], whose view on the syntax-semantics mapping is less strict, but who nevertheless associates presuppositional NPs with high NP positions). Although cases in which there is a one-to-one relation between position and function abound, there are also many cases in which this is not the case, and in which mismatches occur (see Francis and Michaelis [2003] for examples and discussion). To conclude, this means that position and function are not necessarily in a one-to-one correspondence and that the autonomy of syntax thesis is, therefore, still well-supported.

Autosegmental Phonology

J van de Weijer, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The central tenet of autosegmental phonology is that sounds, or, with a technical term, segments (or phonemes) can be split up into smaller units, which can be independently manipulated by phonological operations such as deletion or spreading. A segment is the abstract (or mental) representation of a sound that is postulated in phonology. Speakers of a language are able to split up the continuous speech stream into such smaller units: for instance, although no single sound [t] is ever exactly the same phonetically, hearers are almost always able to recognize and map these different perceptual constructs onto a single segment, notated /t/. This is graphically depicted in (1):

(1)

Phonologists analyze the different shapes a phonological segment can take in different phonetic circumstances (e.g., before a vowel, after a nasal, when unstressed, in rapid speech, when whispered, etc.), and propose rules to describe the distribution of

Autosegmental Phonology

J van de Weijer, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The central tenet of autosegmental phonology is that sounds, or, with a technical term, segments (or phonemes) can be split up into smaller units, which can be independently manipulated by phonological operations such as deletion or spreading. A segment is the abstract (or mental) representation of a sound that is postulated in phonology. Speakers of a language are able to split up the continuous speech stream into such smaller units: for instance, although no single sound [t] is ever exactly the same phonetically, hearers are almost always able to recognize and map these different perceptual constructs onto a single segment, notated /t/. This is graphically depicted in (1):

(1)

Phonologists analyze the different shapes a phonological segment can take in different phonetic circumstances (e.g., before a vowel, after a nasal, when unstressed, in rapid speech, when whispered, etc.), and propose rules to describe the distribution of

different shapes a segment can take, taking into account, for instance, phonetic environment (e.g., word- or syllable-initial consonants are typically realized differently from syllable-final ones; vowels that are stressed differ from vowels that do not have stress). Similar relations between phonological segments and phonetic realizations may also be investigated from a historical point of view: the relations in (1) might also be conceived of as particular instances of historical changes. To the extent that such rules and changes are uniform across languages, they represent important insights into the way in which languages of the world work and how they change. Many rules of realizations are recurrent across languages, but there are also language-particular oddities, which deserve special attention and may as a result become the topic of debate. Research of this type has resulted in the insight that segments often change in small ways, adapting to part of the phonetic environment in which they come to appear, e.g., as a result of morphological concatenation. For instance, a stop that appears before or after a nasal may take over the voicing property of the nasal without becoming a full nasal itself (cf. also below). In a sense, the object of autosegmental phonology is to find out what properties (e.g., voicing, nasality, place of articulation, etc.) can be passed on from one segment to another and what circumstances favor or disfavor sharing such properties (e.g., referring to adjacency of segments as a condition for such processes). In what follows, these aspects will be explored in more detail.

Segments into Features

In this section we will investigate the evidence for the view that phonological segments such as /t/ or /ɛ/ can be decomposed. Questions that arise as a matter of course in such an investigation are: what are the smaller units that make up such a segment? and what kinds of manipulations are possible on these units? A widely accepted answer to the first question is that the smaller units are distinctive features, such as [±voice], [±round], etc. The most comprehensive theory of *distinctive features* is probably that offered by Noam Chomsky and Morris Halle in *The sound pattern of English* (*SPE*; Chomsky and Halle, 1968). In their proposal, which was enormously influential, segments are construed as bundles of distinctive features, such as exemplified for /i/ in (2) (see, for instance, Chomsky and Halle, 1968: 176–177 for a chart of all phonological segments of English analyzed in terms of distinctive features):

(2) /i/

$$\begin{bmatrix} +\text{high} \\ -\text{low} \\ -\text{back} \\ -\text{round} \\ -\text{cons} \\ -\text{nasal} \\ +\text{cont} \\ +\text{tense} \\ \ldots \end{bmatrix}$$

However, the precise characterization of the set of distinctive features is a matter of considerable controversy. In the theory of *SPE*, and lots of work associated with the theory of *generative phonology*, all features can have two values: they are either 'plus' (e.g., [+nasal]) or 'minus' (e.g., [−cont]), and there is no particular structure to the feature set, as (2) clearly shows; all features are formally unrelated to each other, although traditionally (and also in *SPE*) groups of features such as manner features, place of articulation features, and major class features are distinguished.

In the time after 1968, it became apparent that although for some features two values are appropriate, there are also properties of phonological segments that are better expressed by single-valued features, such as a segment that may be a coronal one or not, or whether it is nasal. Indeed, some frameworks have tried to eliminate all binary features in favor of single-valued ones (e.g., dependency phonology, see). We will sidestep this issue here, and instead explore the consequences of the hypothesis that segments can be split up into smaller parts.

Autosegmental Phonology

The first property of phonological segments that was analyzed as a smaller unit that could be manipulated independently was in fact a suprasegmental property, *viz. tone*. John Goldsmith suggested the term 'autosegmental phonology' in his 1976 MIT dissertation that bears the same name, and which dealt with *tonal* phenomena in a number of Bantu languages, and also with a number of other topics that he related to this, such as stress in English and vowel harmony in other languages. In work partly building on earlier results of Bill Leben (Leben, 1973), Goldsmith had the insight that the tones in these languages displayed independent behavior *vis-à-vis* the vowels they normally appeared on. Sometimes a vowel was deleted but the tone that originally appeared on that vowel was saved, and appeared on another vowel in the same

word; sometimes tones disappeared leaving their vowels intact. Finally, it appeared that in such languages strings of tones had independent meaning, i.e., played a role in the grammar without necessarily being associated with particular vowels.

Consider the case of Lomongo (Mongo-Nkundu; a Niger-Congo language spoken in the Democratic Republic of Congo), for instance, in which a rule of intervocalic b-deletion as well as a rule of vowel elision conspire to delete the final vowel of the first part and the initial consonant of the second one in constructions such as the following (after Goldsmith, 1976 [1979]: 33), following Lovins, 1971a, 1971b, glosses checked with the aid of Hulstaert, 1957):

(3)	bàlónó	bǎkáé	→	bàlónǎkáé	'his book'
	book	his			
	bánà	bǎmǒ	→	bánǎmǒ	'other children'
	children	other			
	bǫ̀mǫ̀	bòtámbá	→	bǫ̀mǫ̀támbá	'another tree'
	other	tree			
	bǎtswá là	èmí	→	bǎtswêmí	'you who lead me away'
	go with	me			

In the first of the forms in (3) the final *o* vowel, which has a High tone, is deleted from the first word. The High tone, however, survives this operation and ends up on the first vowel of the second word, the *a* vowel, which already had a Low-High contour tone, and which, as a result, ends up having a High-Low-High contour. In the second form, the final *a* vowel has a Low tone. After deletion of this vowel, no effect is seen on the first vowel of the second part, since the first vowel of this part of the construction has a Low-High contour. Apparently, the Low-Low-High tone structure is automatically converted into, or interpreted as a Low-High contour. This type of automatic operation, in which two identical tones are simplified into a single one, also received a great deal of attention in Goldsmith's work and that of others (e.g., Leben, 1973), and became known as the Obligatory Contour Principle (see also McCarthy, 1986). In the final two forms in (3), the tone preservation (or tone stability) effects are again obvious: in the last form, the three tones (High-Low-Low) on the final vowel of *bǎtswá* and on *là* together make up a High-Low contour on the output form. Thus, in all these forms, the tones are independent of the vowels they occur on: crucially, when a vowel is deleted, this does not necessarily mean that *all* its properties are deleted: in this case, its tonal features remain behind and end up on a different vowel. Goldsmith proposed to formalize this independence by placing different properties of the segment on different autosegmental levels, which are linked by association lines (see e.g., Goldsmith, 1976 [1979]: 19, 23).

We will not go into notational issues, but operations such as tone spreading, as in (3) above, are formalized as follows:

(4)

In this situation, the High tone from the first vowel is delinked, indicated by the broken association line. Rather than being deleted, it re-associates with the vowel on the right, leading to a High-Low tone contour on the second vowel.

At this point, it should be mentioned that the idea of separate levels for separate phonological properties was not new. In his description of the Chinese monosyllable, J. R. Firth (1937) added as a component of phonological description "phonetic properties that must be considered as properties of entire syllables rather than of designated positions within them" (Langendoen, 1968: 50). Obviously, tone was considered to be such a feature, but 'yotization' (i.e., palatalization) and 'labiovelarization' could be considered in the same way (Firth and Rogers, 1937: 91). Another proposal that had similarities with Goldsmith's proposal was made by Zellig Harris and Bernard Bloch (e.g., Harris, 1944; Bloch, 1948), which identifies 'long components', which are phonetic properties that may extend over a number of segments, such as voicelessness or continuancy. See Goldsmith (1976 [1979]: 5ff) for discussion.

Already in Goldsmith's dissertation, the idea of autonomous features was applied to phenomena other than tone. Goldsmith (1976 [1979]: 150 ff) discusses vowel harmony, which refers to the phenomenon that vowels in a certain domain (usually the phonological word) must agree for a specific feature, i.e., all bear the same value for roundness, height, backness, or a combination of features. Vowel harmony occurs in many African languages, but also in others, such as Turkish and Finnish. To describe *vowel harmony*, the idea that distinctive features are not necessarily part of individual segments is also extremely useful: rather in such languages, distinctive features such as [+round] or [−back] are properties of **larger** domains than individual segments, such as the word, and are therefore allowed to link (formally in the same way as

the tone in [4] links to the vowel) to all available positions in the word. This is exemplified for front/back harmony in (5):

(5)

Cases of harmony therefore provided evidence for which features could display autosegmental behavior, and the extent to which different types of vowel harmony are found (cf. van der Hulst and van de Weijer, 1995 for an overview of issues involved); these provide evidence for the existence and autosegmental activity of different distinctive features. Harmony-like behavior has also been reported for some consonantal properties, such as anteriority (e.g., Shaw, 1991), while particular laryngeal properties, such as voicing, aspiration, and glottalization, also display cross-consonantal harmony-like effects (for instance, these properties may be tolerated if and only if they appear on all consonants in a word; see, e.g., Kehrein, 2002: Chap. 3).

Feature Grouping

The discussion in the previous section has shown that there are a number of features that can display independent, autosegmental behavior. One aspect of feature theory, already hinted at above, has not thus far been captured by autosegmental theory, namely that different features may delink or assimilate **together**, i.e., not alone but together with features of the same kind. A straightforward example of this involves Place assimilation. Many languages have a rule in which a coronal nasal assimilates in place of articulation to a following stop: this may happen in the morphology or in phrasal phonology, as the examples in (6) show:

(6a) *in+possible* → *i*[m]*possible*
in+consistent → *i*[ŋ]*consistent*
in+tolerable → *i*[n]*tolerable*

(6b) *i*[m] *Boston*
i[ŋ] *Goa*
i[n] *Toledo*

Obviously what is involved in these cases is autosegmental spreading of *all and only* Place features from the stop to the nasal (cf. [4] above for the similarity in formalism):

(7)

Obviously, we wish to maintain that the **same** rule takes place for all possible processes of Place assimilation in a particular language, i.e., we want to read the label 'Place' in representations such as (7) to stand for any place feature, whether this refers to labial, coronal, dorsal place, or in fact to any other place of articulation. One influential way in which this insight has been captured is by assuming that individual Place features are attached to a higher, organizing Place **node**, just like there is a higher node, usually referred to as the **root**, which dominates **all** features, so that manipulations of entire segments, such as deletion or insertion, can also be described in the autosegmental format that we have used so far.

Another situation in which an organizing node is useful is when all features of the same type are disallowed in particular positions. Consider the case of languages like Thai, for instance, which have a contrast between aspirated, voiced, and voiceless stops in the initial position of the word, but disallow any contrasts at the end of the syllable. For such languages, it may be assumed that any Laryngeal feature (whether this refers to voicing, aspiration or – for other languages – glottalization) is disallowed in syllable-final position. Here are some standard examples from Thai, in which initial voiced, voiceless, and aspirated stops contrast (from Kenstowicz, 1994: 38):

(8) dam 'black'
tam 'to pound'
t^ham 'to do'

In final position in Thai, only a plain voiceless stop [t] is permitted. To describe this in a uniform manner, the autosegmental formalism may incorporate a Laryngeal node, which is then delinked, or disallowed, in syllable-final position:

(9a) Delinking of a final Laryngeal node

(9b) Constraint against a final Laryngeal node

The constraint in (9b) says that representations with a final Laryngeal node are ill-formed (cf. Lombardi, 1995, 1999 for the implications of this line of inquiry).

The idea of autosegmental features that are organized with intermediate nodes, such as Place and Laryngeal, leads to a tree-like model of the segment. For the past 20 years, there has been a great deal of discussion about the exact species of the tree, centering around such questions as which features exactly are needed, which organizing nodes are needed, and the way in which the highest node (the root) links to higher-level prosodic structure. Probably the most widely cited and influential proposal was that made by Elisabeth Sagey in her 1986 MIT dissertation (Sagey, 1986; see also Clements, 1985). However, the debate as to whether there is one geometry for all languages continues to the present day, although in recent years this debate has been overshadowed somewhat by controversies regarding the content and nature of phonological manipulations: are these rule-like, autosegmental operations (as in [9a] above), or is the relation between underlying representation and output form best captured by way of a hierarchy of mutually ordered constraints (such as [9b] above), as proposed in recent work within the *optimality theory* framework (Prince and Smolensky, 1993, and much later work)? For many cases, the distinction may not matter, in the sense that autosegmental representations may play similar roles in either rules or constraints (as [9] shows), although the specific role of relations between features, both within the segment and across segments, remains a topic of active inquiry.

Avestan

E Tucker, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Avestan is the language of the most ancient collection of texts sacred to the Zoroastrian religion. It represents the Old Iranian stage of the Iranian language family, and provides, along with Old Persian, the earliest evidence for the Iranian branch of the Indo-Iranian and Indo-European language families. The language is known only via a defective medieval manuscript tradition, which was preserved in Iran and also in India, to which adherents of the Zoroastrian faith, the Parsis, emigrated according to tradition in 10th-century A.D. Hence its study presents a range of philological, textual, and interpretative problems.

Two forms of the language are documented: Old Avestan (OAv.; sometimes called Gathic Avestan) and Younger Avestan (YAv.). Opinion is at present divided as to whether they represent earlier and later forms of precisely the same language, or whether dialect differences are also involved. A difficulty is that OAv. is known only from a very small number of texts: the Gāthās, seventeen complex poems in five different meters attributed to the prophet Zarathuštra himself, which still present many problems of interpretation; two short sacred prayers; and a traditional liturgy in seven sections, the Yasna Haptaŋhāiti. The most extensive surviving Avestan texts, that is, the other parts of the 72-chapter Yasna, the lengthy Yašts, which honor divinities such as Mithra and Anāhitā, and the Vīdēvdāt, 'the Law which rejects False Gods' are composed in YAv. A few short sections of the Yasna are in YAv. with an artificial veneer of OAv. phonological features (pseudo-OAv.). Faulty grammar in parts of the Avesta may suggest that composition continued at a stage when Avestan was no longer a living language, but the text may also have deteriorated during transmission.

Absolute dates for Avestan are entirely lacking. The date of the prophet Zarathuštra is still debated, but many scholars agree that the Gāthās must be roughly contemporary with the RigVeda in India (i.e., toward the end of the second millennium B.C.), as OAv. morphology and syntax are on a par with those of the earliest Vedic language. YAv. shows many simplifications, particularly in its verb system, and innovations, and the text collection as a whole must span several centuries.

Avestan diverges from Old Persian in some important sound changes (IE **ḱ, ǵ, ǵh* > Av. *s, z, z*, but > OP *θ, d* [δ], *d* [δ]; IE **ḱu̯, ǵu̯* > Av. *sp, zb*, but OP *s, z*), but in these respects it agrees with the majority of Iranian languages. It is often described as East Iranian because geographical names found in the YAv. texts refer to the region of present day Afghanistan and East Iran and none refer to West Iran. However, Avestan does not share in the most characteristic features known from Middle Iranian languages of the extreme East, such as Khotanese. Rather it shows several phonological developments (if these do indeed belong to the original Avestan language) that are unparalleled elsewhere in Iranian (**-aha-* > *-aŋha-*, **-ft-* > *-pt-*, **-rt-* > *-š̰-* when the syllable was accented, etc.). No Iranian language known from later times can be identified as a direct descendant of Avestan.

The Avestan texts were composed orally, and they were recited and transmitted orally by the Zoroastrian priesthood in different regions of Iran, but it is hard, if not impossible, to assign specific features of Avestan to influence from specific local languages. The written recension was only made during the Sasanian period (224–651 A.D.), when Zoroastrianism flourished as the state religion. An elaborate alphabet of 53 signs, including 16 for vowels, was invented on the basis of the cursive Zoroastrian Pahlavi script and the Christian Psalter script (both derived from Aramaic) in order to record as precisely as possible the traditional pronunciation of Avestan, which had ceased to be a living language several centuries earlier. Avestan orthography is not based on phonemic principles, but it conveys a wealth of information about allophonic variation. Consequently, Avestan words often look very different from their exact counterparts in Vedic, even though the languages are closely related; contrast YAv. *hāuuōiia-*: Vedic *savya-* 'left' or OAv. *məŋghī*: Vedic *maṁsi* 'I thought.' Moreover, morphological regularities within the Avestan language itself are often obscured (e.g., *barahi, baraiti, bareṇti* represent 2 sg., 3sg., 3pl. present active based on the inherited thematic stem *bara-* 'bear,' cf. Skt. *bharasi, bharati, bharanti*).

The Avestan manuscripts, of which the earliest dates from 13th-century A.D., reflect a written tradition that barely survived the centuries following the Islamic conquest. At one stage only a single manuscript existed for each part of the extant Avesta, and approximately three-quarters of the Avesta as described in the Sasanian Zoroastrian books has been lost. Recent scholarship has made progress in reconstructing the spellings of the 'Sasanian Archetype' text, but it is still often difficult to determine which features belong to the original Avestan language and which arose in the course of either oral or

written transmission. According to some scholars, the phonology of OAv. was close to that of Proto-Iranian, and Gathic meter may provide evidence for archaic features such as the vocalization of semivowels according to Sievers' Law, and a hiatus between vowels caused by the recent loss of laryngeals.

The inflectional morphology of both OAv. and YAv. is extremely rich. For nouns, adjectives and pronouns, the full set of eight IE case inflections and three numbers remain alive, with a huge range of nominal stem types, and some ancient irregular paradigms, such as YAv. *paṇtå̊* (nom.), *paϑō* (gen.) 'path'; OAv. *huuarə* (nom.), *xᵛəṇg* (gen.) 'sun'; OAv. *aogō* (nom.), *aojaŋhā* (instr.) 'strength.' The OAv. enclitic acc. pl. personal pronouns *nå̊* 'us,' *vå̊* 'you' (cf. Latin *nōs, vōs*) are an archaism not found elsewhere in Indo-Iranian. At the same time, there are innovations, such as the OAv. (and YAv.) nom. pl. masc. ending *–ā* in thematic stems (more frequent than inherited *-å̊*, *-å̊ŋhō*), and the creation in YAv. of a distinct ablative singular inflectional ending for all nominal classes.

In the OAv. verb system all the IE tense-aspect stems (present, aorist, perfect) are fully employed. YAv. has a much simplified system where present and preterite are based on a single stem (the inherited present) and distinguished by different inflectional endings. The inherited augment *a-* rarely appears, and its function in Av. is problematic. Although thematic presents are productive, the rarer types of athematic present are well represented, notably acrostatic root presents (OAv. *stāumī* 'I praise,' *aogədā* 'he said,' YAv. *å̊ŋhāire* 'they sit'). Modal forms (subjunctives, optatives, and imperatives) are frequent at all stages.

The Avestan lexicon is remarkably free of loanwords from non-Iranian languages, and it preserves some IE lexemes that were lost in Indo-Aryan, e.g., *varəz-* 'to work,' *vad-* 'to lead.' Contrasting vocabulary items for good (ahuric) versus evil (daevic) beings reflect Zoroastrian dualism but their linguistic origins are complex (e.g., *staman-/ zafar-* 'mouth,' *dōiϑra-/ aši-* 'eye,' *aog-/ dauu-* 'to speak,' *tak-/ zbar-* 'to run,' *nmāna-/ gərəδa-* 'house,' *ϑβərəs-/ karət-* 'to fashion').

Aymara

W F H Adelaar, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The name 'Aymara' is used for one of the most important native languages of South America. It is spoken by approximately 2 000 000 people in three countries: Bolivia (mainly in the department (administrative division) of La Paz, but also in parts of Cochabamba, Oruro, and Potosí), Chile (in the highlands of Tarapacá), and Peru (in the departments of Moquegua, Puno, and Tacna). Aymara is closely related to the Jaqaru language – spoken by less than a 1000 people, mainly in the village of Tupe in the province of Yauyos (department of Lima) in central Peru – as well as to Cauqui, spoken by a few individuals in the nearby village of Cachuy. Together, the languages Aymara, Jaqaru, and Cauqui form a family that has variously been called 'Jaqi' (Hardman, 1978), 'Aru' (Torero, 1972), 'Aimara' (Cerrón-Palomino, 2000), and 'Aymaran,' which is the name used in this article.

The Aymaran language family has no proved external relatives. There are close and detailed similarities in the phonological, structural, and lexical domains with the neighboring Quechua language group; the two groups also share more than 20% of their lexicon. This situation suggests a protracted period of interaction between the underlying protolanguages of both Aymaran and Quechua. The interaction may have continued on a local basis during the further

written transmission. According to some scholars, the phonology of OAv. was close to that of Proto-Iranian, and Gathic meter may provide evidence for archaic features such as the vocalization of semivowels according to Sievers' Law, and a hiatus between vowels caused by the recent loss of laryngeals.

The inflectional morphology of both OAv. and YAv. is extremely rich. For nouns, adjectives and pronouns, the full set of eight IE case inflections and three numbers remain alive, with a huge range of nominal stem types, and some ancient irregular paradigms, such as YAv. *paṇtå̊* (nom.), *paϑō* (gen.) Aymara

W F H Adelaar, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The name 'Aymara' is used for one of the most important native languages of South America. It is spoken by approximately 2 000 000 people in three countries: Bolivia (mainly in the department (administrative division) of La Paz, but also in parts of Cochabamba, Oruro, and Potosí), Chile (in the highlands of Tarapacá), and Peru (in the departments of Moquegua, Puno, and Tacna). Aymara is closely related to the Jaqaru language – spoken by less than a 1000 people, mainly in the village of Tupe in the province of Yauyos (department of Lima) in central Peru – as well as to Cauqui, spoken by a few individuals in the nearby village of Cachuy. Together, the languages Aymara, Jaqaru, and Cauqui form a family that has variously been called 'Jaqi' (Hardman, 1978), 'Aru' (Torero, 1972), 'Aimara' (Cerrón-Palomino, 2000), and 'Aymaran,' which is the name used in this article.

The Aymaran language family has no proved external relatives. There are close and detailed similarities in the phonological, structural, and lexical domains with the neighboring Quechua language group; the two groups also share more than 20% of their lexicon. This situation suggests a protracted period of interaction between the underlying protolanguages of both Aymaran and Quechua. The interaction may have continued on a local basis during the further

development and expansion of both language groups. The close similarities between the two language groups have often been interpreted as a proof of common origin (the so-called Quechumaran hypothesis). Nevertheless, most similarities are attributable to linguistic convergence, making it difficult to distinguish between borrowed and inherited material (*see* **Andean Languages; Quechua**).

Before 1600, Aymara and related dialects were widely spoken in southern Peru and in the eastern and southern Bolivian highlands, where Quechua is now the dominant language. The historical influence of Aymara through borrowing can be appreciated from the spread of Aymara numerals into the southern cone of South America (Mapuche) and into the Amazonian basin (Tacanan languages). The name 'Aymara' is probably derived from a province or ethnic group located in the present-day Peruvian department of Apurimac (now Quechua speaking). The study of the Aymara language received an important stimulus in the 17th century when the Jesuit order established a mission in Juli, on the southwestern shore of Lake Titicaca. The first grammar and dictionary of Aymara were written in 1603 and 1612, respectively, by a Jesuit, Ludovico Bertonio.

The Aymara vowel system consists of three vowels (*a*, *i*, *u*), of which the high vowels are lowered to (*e*, *o*) next to a uvular consonant. There is a distinction of vowel length that is mainly used in morphology, but also in a few lexical roots. Stops and affricates are normally voiceless; they can be plain, glottalized, or aspirated. There is a contrast between velar and uvular consonants. Dialects in the border area of Bolivia, Chile, and Peru have a distinctive velar nasal consonant. Stress is predictable and is located on the penultimate syllable or mora. All roots are vowel final. However, the final vowel of a nominal expression is regularly deleted before pause. Although the structure of Aymara roots and suffixes is basically simple, surface forms can be complex due to the fact that many suffixes trigger the suppression of a preceding vowel. This suppression must be treated as a formal property of the suffix in question, because there are no synchronically valid phonological rules to account for it. In some cases, root-interior vowels are also suppressed under similar circumstances. These different types of vowel suppression produce elaborate consonant clusters, as illustrated in *han unxtkiri* 'without moving,' 'immobile,' which can be analyzed as follows (vowels between parentheses are suppressed; PROG, progressive; AGT, agent; NOM, nominalizer):

(1) han(i) un(u)q(i)-t(a)-k(a)-iri
not rock-upward/begin-PROG-AGT.NOM

The combination *unxta-* (< unuqi-ta-) is fixed and is interpreted as 'to move slightly.'

Aymara has an agglutinating structure mainly based on suffixation; there are no prefixes at all. The morphology is complex, but regular. Words containing as many as nine consecutive suffixes are no exception (the fixed combination *aru-si-* means 'to speak'; INCL, inclusive; REFL, reflexive; PL, plural; COMPL, completive; BEN, benefactive):

(2) hiwas-kam(a) aru-s(i)-kipa-si-p-xa-ña-naka-taki-sa
we(INCL)-case:among speak-REFL-turn-REFL-PL-COMPL-NOM-PL-case:BEN-too
'so that we are able to communicate among ourselves'

Verb-final order is obligatory in dependent clauses and is the preferred order in full sentences. In noun phrases, all modifiers precede their heads. Nouns can be marked for case, number (plural), and person of possessor. The overall structure of the language is nominative–accusative. Case is expressed by suffixes, but the accusative is marked by eliminating a stem-final vowel. There is a four-term pronominal system consisting of speaker (*naya* 'I'), addressee (*huma* 'you'), third person (*hupa* 'he/she'), and an inclusive plural that comprises both speaker and addressee (*hiwasa*). This system is also reflected in nominal possession and in verbal inflection.

Verbs in Aymara exhibit a rich derivational morphology, including causative, reflexive–reciprocal, spatial direction, number of subject, aspect, speaker orientation ('hither'), and several other options. Tense, mood, and personal reference, both of the subject and of a human (in)direct object, are combined in complex portmanteau endings, which are a hurdle for the nonnative learner. In these endings (nine for each tense or mood paradigm), a third-person object is not explicitly indicated. Characteristic for the Aymara verb is the existence of evidential distinctions (inference, conjecture, nonpersonal witness, etc.), for which the Aymara society is highly sensitive.

Verbalizations – copula 'to be,' locative verb 'to be at' – are indicated morphologically, the former by vowel lengthening (1POSS, first-person possessor; VERBAL, verbalizer; 2SUB, second-person subject; ASSERT, assertive):

(3) hič^{h}a-x(a) wawa-ha-:-x(a)-ta-wa.
now-topic child–1POSS-VERBAL :be-COMPL – 2SUB-ASSERT
'Now you are already my child.'

Nominalization plays an important central role in Aymara morphosyntax. Different types of dependent

clauses are obtained by combining nominalized verbs with specific case markers. Nominalization is also used to form relative clauses. In contrast to Quechua, person of object cannot be indicated morphologically in nominalized verbs. (Note: Examples (1)–(3) are from Albó and Layme (1992)).

Azerbaijan: Language Situation

E Bishop, The University of Texas, Austin, Texas, USA

© 2006 Elsevier Ltd. All rights reserved.

A former republic of the Soviet Union, the Republic of Azerbaijan became independent in 1991. The main language of Azerbaijan is Azerbaijani (North Azerbaijani). Article 21 of the Republic's constitution notes that "the Azerbaijan language shall be the state language of Azerbaijan." Among the languages of the republic's residents, three language groups are currently represented: Turkic speakers (around 89%), Russian speakers (3%), and Armenian speakers (2%, most of whom are resident in the Nagorno-Karabakh district). The remaining six percent of the population are native speakers of Georgian, Lezgin (Lezgi), Talysh, Avar, Tatar, Tat, Tsakhur, or Kurdish (Kurmanji). Public affairs and higher education require linguistic minorities to use Azerbaijani.

Native speakers of Azerbaijani reside, in addition to the Republic of Azerbaijan (where North Azerbaijani is spoken), in Iran (South Azerbaijani), Dagestan, Georgia, Turkey, Syria, and Iraq. North Azerbaijani is marked by Russian loanwords, and South Azerbaijani is distinguished by Persian loanwords.

Ninety eight percent of those who speak Azerbaijani consider it their first language. Periodicals have been printed in it since the mid-19th century. Azerbaijani was written in the Arabic script until 1924, when the Latin alphabet was introduced. In 1939, the Cyrillic alphabet – used to write Russian – replaced it. Literacy among North Azerbaijani speakers neared 100% by 1970. During 1991, the Republic of Azerbaijan's legislature approved a third reform, to use the 'new Roman' alphabet. At the end of the Soviet era, the Republic of Azerbaijan published 151 newspapers, of which 131 were in the official language.

One of the southern branch of the Altaic family of languages, Azerbaijani is not an Indo-European language. With the Anatolian Turkish spoken in Turkey, Turkmen spoken in Turkmenistan, and dialects of Crimean Tatar, Azerbaijani forms the Oghuz or southwestern Turkic family of languages. Like other Turkic languages, those who speak Azerbaijani add suffixes to fixed noun stems to indicate gender and number. Verbs agree with their subjects in case and number and have voice, tense, mood, and nonfinite forms.

Marked by archaic characteristics that are absent in modern Turkish, Azerbaijani is closer to the Ottoman Empire's official language. Like Ottoman Turkish, it also bears the influence of Arabic in its vocabulary and grammar. Azerbaijani has nine vowels and 23 consonants. As with other Turkic languages, it requires vowel harmony: vowels of suffixes must harmonize with the vowels of noun and verb stems.

In Azerbaijan, the Institute of Linguistics (named after the poet Naizami) sponsors research. The institute, which supports the study of written and spoken Azerbaijani, as well as poetics and folkloric studies, has been affiliated with the Azerbaijani National

clauses are obtained by combining nominalized verbs with specific case markers. Nominalization is also used to form relative clauses. In contrast to Quechua, person of object cannot be indicated morphologically in nominalized verbs. (Note: Examples (1)–(3) are from Albó and Layme (1992)).

Azerbaijan: Language Situation

E Bishop, The University of Texas, Austin, Texas, USA

© 2006 Elsevier Ltd. All rights reserved.

A former republic of the Soviet Union, the Republic of Azerbaijan became independent in 1991. The main language of Azerbaijan is Azerbaijani (North Azerbaijani). Article 21 of the Republic's constitution notes that "the Azerbaijan language shall be the state language of Azerbaijan." Among the languages of the republic's residents, three language groups are currently represented: Turkic speakers (around 89%), Russian speakers (3%), and Armenian speakers (2%, most of whom are resident in the Nagorno-Karabakh district). The remaining six percent of the population are native speakers of Georgian, Lezgin (Lezgi), Talysh, Avar, Tatar, Tat, Tsakhur, or Kurdish (Kurmanji). Public affairs and higher education require linguistic minorities to use Azerbaijani.

Native speakers of Azerbaijani reside, in addition to the Republic of Azerbaijan (where North Azerbaijani is spoken), in Iran (South Azerbaijani), Dagestan, Georgia, Turkey, Syria, and Iraq. North Azerbaijani is marked by Russian loanwords, and South Azerbaijani is distinguished by Persian loanwords.

Ninety eight percent of those who speak Azerbaijani consider it their first language. Periodicals have been printed in it since the mid-19th century. Azerbaijani was written in the Arabic script until 1924, when the Latin alphabet was introduced. In 1939, the Cyrillic alphabet – used to write Russian – replaced it. Literacy among North Azerbaijani speakers neared 100% by 1970. During 1991, the Republic of Azerbaijan's legislature approved a third reform, to use the 'new Roman' alphabet. At the end of the Soviet era, the Republic of Azerbaijan published 151 newspapers, of which 131 were in the official language.

One of the southern branch of the Altaic family of languages, Azerbaijani is not an Indo-European language. With the Anatolian Turkish spoken in Turkey, Turkmen spoken in Turkmenistan, and dialects of Crimean Tatar, Azerbaijani forms the Oghuz or southwestern Turkic family of languages. Like other Turkic languages, those who speak Azerbaijani add suffixes to fixed noun stems to indicate gender and number. Verbs agree with their subjects in case and number and have voice, tense, mood, and nonfinite forms.

Marked by archaic characteristics that are absent in modern Turkish, Azerbaijani is closer to the Ottoman Empire's official language. Like Ottoman Turkish, it also bears the influence of Arabic in its vocabulary and grammar. Azerbaijani has nine vowels and 23 consonants. As with other Turkic languages, it requires vowel harmony: vowels of suffixes must harmonize with the vowels of noun and verb stems.

In Azerbaijan, the Institute of Linguistics (named after the poet Naizami) sponsors research. The institute, which supports the study of written and spoken Azerbaijani, as well as poetics and folkloric studies, has been affiliated with the Azerbaijani National

Academy of Sciences, founded in 1945. The institute does not sponsor research in minority languages, poetics, or folklore.

Azerbaijani speakers in Iran are more numerous than those in Azerbaijan (13 to 30 million in northern Iran, 6 million in the Republic of Azerbaijan). In Iran, Azerbaijani speakers reside in the Caspian Sea provinces; those of Tabriz and its surrounding areas speak a dialect distinct from that of a second, Southern dialect group. Outside of the Republic, these speakers have no official status, so secondary and higher education in Azerbaijani are not available to them.

Azerbaijani is taught as a foreign language throughout the world. For example, in the United States, where, for purposes of university administration, Azerbaijani is considered a less commonly taught language, it is taught at the University of California at Los Angeles, Indiana University, New York State University at Geneseo, Cameron University, and at the Foreign Service Institute.

Azerbaijanian

L Johanson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Location and Speakers

Azerbaijanian (Azerbaijani, Azeri) (*Azərbaycan dili, Azərbaycanca*) belongs, like Turkish, to the western group of the southwestern, or Oghuz, branch of the Turkic language family. It is spoken in northern and southern Azerbaijan (i.e., in the Republic of Azerbaijan), particularly in the province of Azerbaijan, and in Iran. Azerbaijanian is the official language of the Republic of Azerbaijan (*Azərbaycan Respublikası*), which constitutes the easternmost part of Transcaucasia. The Republic is situated between Iran and Russia, with a small European portion north of the Caucasus range. It includes the exclave of the Nakhchivan Autonomous Republic and the separatist Nagorno–Karabakh region. It borders on the Russian Federation in the north, Georgia in the northwest, Armenia in the west, Iran in the south, and the Caspian Sea in the east. Azerbaijanians make up about 90% of the Republic's total population of about 7.8 million. Other ethnic groups include Dagestanis, Russians, and Armenians (mainly in Nagorno-Karabakh). Over 80% of the citizens speak Azerbaijanian as their first language. The number of speakers in the Republic amounts to about 7 million. The standard language is based on the dialect of the capital Baku (*Bakı*). The number of speakers in southern Azerbaijan, which is located in northwestern Iran and borders on Turkey in the west, is estimated to be over 13 million. Similar varieties are spoken in eastern Anatolia, northern Iraq, Georgia, and Armenia. The total number of speakers may amount to 20 million.

The current status of the language in the Republic is very solid. More than half of Azerbaijani speakers are monolingual. The social situation of the varieties of Azerbaijani spoken in Iran is quite different. There the languages have not been promoted; on the contrary, their use has been discouraged and public use of Azerbaijani was banned for several decades. The situation is now improving.

Origin and History

The language goes back to the Oghuz Turkic varieties of the Seljuks, who immigrated to the area in the 10th and 11th centuries. These people originally belonged to the Oghuz confederation of tribes, whose Inner Asian steppe empire collapsed in 744. Due to political and religious differences, Azerbaijanian Turks for centuries lived in relative separation from the Turks of Turkey. Azerbaijan's history shows substantial cultural influence from Iran. In 1828, Azerbaijan was divided into a northern and a southern part under Russian and Persian rule, respectively. Northern Azerbaijan was part of the former Soviet Union for 70 years. It regained independence in 1991.

Related Languages and Language Contacts

The language is related to Turkish, Gagauz, South Oghuz, Khorasan Turkic, and Turkmen. It has a

Academy of Sciences, founded in 1945. The institute does not sponsor research in minority languages, poetics, or folklore.

The current status of the language in the Republic is very solid. More than half of Azerbaijani speakers are monolingual. The social situation of the varieties of Azerbaijani spoken in Iran is quite different. There the languages have not been promoted; on the contrary, their use has been discouraged and public use of Azerbaijani was banned for several decades. The situation is now improving.

Origin and History

The language goes back to the Oghuz Turkic varieties of the Seljuks, who immigrated to the area in the 10th and 11th centuries. These people originally belonged to the Oghuz confederation of tribes, whose Inner Asian steppe empire collapsed in 744. Due to political and religious differences, Azerbaijanian Turks for centuries lived in relative separation from the Turks of Turkey. Azerbaijan's history shows substantial cultural influence from Iran. In 1828, Azerbaijan was divided into a northern and a southern part under Russian and Persian rule, respectively. Northern Azerbaijan was part of the former Soviet Union for 70 years. It regained independence in 1991.

Related Languages and Language Contacts

The language is related to Turkish, Gagauz, South Oghuz, Khorasan Turkic, and Turkmen. It has a

strong Iranian substrate and has for many centuries been in close direct contact with Persian. Turkish had a considerable influence on the northern Azerbaijanian standard language as established before the Soviet era. During the past century, Russian has influenced the standard language, whereas the contacts with Turkish have been very limited. There is nevertheless a high degree of interintelligibility with Anatolian Turkish.

An Azerbaijanian koiné functioned for centuries as a lingua franca, serving trade and intergroup communication all over Persia, in the Caucasus region and in southeastern Dagestan. Its transregional validity continued at least until the 18th century. Later on, it lost its importance in favor of Persian in the south, whereas Russian was dominant in the north. In the period of Russian domination of economy and politics, Russian had a strong position; 38% of the Azerbaijanians of the Republic still speak Russian fluently.

The Written Language

The early history of Azerbaijanian as a literary language is closely linked to that of Anatolian Turkish. Signs of its detachment are found in sources written at the end of the 14th century. Azerbaijanian has a long and rich literary tradition. The language was written in Arabic script up to the 20th century. In 1923, a Latin-based script, *yaŋalif* 'the new alphabet,' was introduced in Soviet Azerbaijan. It was a model for the Roman alphabet that was introduced in Turkey in 1928. This alphabet was replaced by a Cyrillic script in 1939–1940. In 1991, after the disintegration of the Soviet Union, the Republic of Azerbaijan adopted a new modified Roman-based alphabet incorporating a few special letters. The transition to this script has been gradual. The Republic still applies a dual script system, with the Roman- and Cyrillic-based letters appearing side by side. In southern Azerbaijan, where the written use of the language is highly restricted, the Arabic script is still used.

Distinctive Features

The language exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. In the following discussions, only a few distinctive features will be dealt with – in particular, some ways in which Azerbaijanian is different from Turkish. In the notation of suffixes, capital letters indicate phonetic variation, e.g., A = a/e, I = ï/i. Segments in parentheses occur after vowel-final or consonant-final stems. Hyphens are used here to indicate morpheme boundaries.

Phonology

Unlike Turkish, Azerbaijanian has a mid vowel phoneme *e* and a higher phoneme *ė* (e.g., *ėl* 'people, country' vs. *el* 'hand' and *ėn* 'width' vs. *en* 'most'). In words of Arabic–Persian origin, non-high-position vowels are more fronted than they are in Turkish (e.g., *teref* 'side' vs. Turkish *taraf*). Common Turkic initial *y-* is often lost before high vowels (*üz* 'face' (Turkish *yüz*) and *ulduz* 'star' (Turkish *yıldız*)). Initial *ï-* is replaced by *i-* (*il* 'year' (Turkish *yıl*)). Vowels are often rounded in the neighborhood of *v* (*ov* 'hunt' (Turkish *av*)).

The spoken language is relatively conservative with respect to sound harmony. It still displays invariable suffixes – i.e., suffixes not subject to sound harmony (*gel-dox* [come-PAST-1.PL], *gel-dïx* [come-PAST-1.PL] 'we came' and *išle-max* [work-INF] 'to work'); cf. Turkish *gel-dik* [come-PAST-1.PL] and *işlemek* [work-INF] (with front–back and rounded–unrounded harmony). In the standard language, the vowel harmony is normalized on the standard Turkish model, e.g., *it-ler-imiz-den* [dog-PL-POSS.1. PL-ABL] (front vowels) 'from our dogs' vs. *at-lar-ïmïz-dan* [horse-PL-POSS.1.PL-ABL] (back vowels) 'from our horses.' A few suffixes are invariable. As in Turkish, rounded vs. unrounded harmony does not affect low suffix vowels.

Common Turkic initial *q-* is, as in Turkmen, represented by the back-voiced stop *ġ-*, e.g., *ġara* 'black' (Turkish *kara*). Common Turkic final back *-q* is represented by *-ġ* in polysyllabic words and in certain monosyllabic words (after originally long vowels), e.g., *ayaġ* 'foot' (Turkish *ayak*), *aġ* 'white' (Turkish *ak*). It is fricativized to *-x* in other cases (*yox* 'nonexistent' (Turkish *yok*)). Stem-internal *q* is also fricativized (*yaxïn* 'near' (Turkish *yakin*)). The voicing of Common Turkic *k-* generally follows the same pattern as in Turkish (*gör-* 'to see' < *kör-*). There are, however, some differences, as for *kėč-* 'to pass' vs. Turkish *geç-*. The distribution of the initial dentals *t-* and *d-* is generally the same as in Turkish (*diš* 'tooth' < *ti:š*). Exceptions include *tik-* 'to sew' (Turkish *dik-*) and *daš* 'stone' (Turkish *taş*). The distribution of the initial labials *p-* and *b-* mostly follows the Turkish pattern. Exceptions include *barmaġ* 'finger' (Turkish *parmak*) and *poz-* 'to destroy' (Turkish *boz-*). As in most Turkic languages, the initial nasal *m-* occurs instead of *b-* as a result of assimilation to a following nasal (*min* 'thousand' (Turkish *bin*)). Glottal *h* and uvular *x*, which have merged into *h* in Turkish, are

distinct phonemes (e.g., *heyat* 'life' (Turkish *hayat*) and *xeber* 'information' (Turkish *haber*)). A word-medial glottal stop occurring in loans of Arabic origin may be pronounced or realized as vowel length, as in *te'sir* or *te:sir* 'influence.' Unvoiced obstruents may be strongly aspirated, as in $t^h op^h$ 'gun, cannon.' The stops *k* and *g* are strongly palatalized in many dialects. Consonant metathesis is a rather common phenomenon (*ireli* 'front' (Turkish *ileri*) and *körpü* 'bridge' (Turkish *köprü*)).

Grammar

The dative forms of the pronouns *men* 'I' and *sen* 'you' are *mene* [I-DAT] and *sene* [you-DAT] (Turkish *bana*, *sana*). The marker *-(y)Ar*, corresponding to Turkish *-(V)r*, forms a general, less focused present tense with habitual, intentional, prospective, and similar meanings (e.g., *bil-er* [know-AOR] 'knows, will know' (Turkish *bil-ir* [know-AOR]) and *gel-er* [come-AOR] 'comes, will come' (Turkish *gel-ir* [come-AOR])). The present-tense marker *-(y)Ir* corresponds to Turkish *-Iyor* and Turkmen *-yA:r*, as in *yaz-ïr* [write-PRES] 'writes, is writing' (Turkish *yaz-iyor* [write-PRES]) and *iste-yir* [want-PRES] 'wants' (Turkish *istiyor* [want-PRES]). Unlike in Turkish, low vowels have thus been generalized in *-(y)Ar*, whereas high vowels have been generalized in *-(y)Ir*. The first-person copula suffixes of the pronominal type are *-(y)Am* (e.g., *gör-ür-em* [see-PRES-1.SG] 'I see,' *al-ïr-am* [take-PRES-1.SG] 'I take,' *gör-ür-ük* [see-PRES-1.PL] 'we see,' and *al-ïr-ïğ* [take-PRES-1.PL] 'we take' vs. Turkish *gör-üyor-um* [see-PRES-1.SG], *al-iyor-um* [take-PRES-1.SG], *gör-üyor-uz* [see-PRES-1.PL], and *al-iyor-uz* [take-PRES-1.PL]). The second-person singular copula suffix is *-sAn*, as in *gözel-sen* [beautiful–2.SG] 'you are beautiful' (Turkish *güzel-sin* [beautiful–2.SG]). The perfect paradigm contains first-person forms with *-mIš*, whereas *-(y)Ib* is used in the second and third persons (e.g., *gel-miš-em* [come-PERF-1.SG] 'I have come,' *gel-ib-sen* [come-PERF-2.SG] 'you have come,' and *gel-ib-*[*dir*] [come-PERF-(3.SG)] 'has come'). The perfect markers are not used as the corresponding Turkish *-mIş* markers, which have indirective meaning. Thus, forms such as *ġoy-muš -am* [put-PERF-1.SG] 'I have put' and *al-miš-am* [take-PERF-1.SG] 'I have taken' are translated into Turkish by *koy-d-um* [put-PAST-1.SG] and *al-d-im* [take-PAST-1.SG] rather than by *koy-muş -um* [put-EV-1.SG] and *al-miş -im* [take-EV-1.SG]. The Persian influence on the dialects varies considerably. Some varieties use the comparative suffix *-ter* and the superlative suffix *-teri:n*, both copied from Persian.

Though the syntax is rather similar to that of most other Turkic languages, the Persian impact has been considerable, especially in the southern varieties. Many conjunctions and other functional words are copied from Persian and Arabic (via Persian), e.g., *ki,* which precedes complement and relative clauses.

Lexicon

Due to the different political and cultural developments for the past 600 years, the Azerbaijanian vocabulary differs from the modern Turkish vocabulary in many respects. There are certain differences in the genuinely Turkic lexicon (*tap-* 'to find' vs. Turkish *bul-*, *öz* 'self' vs. *kendi*, *isti* 'warm' vs. *sıcak*, *düš* 'to go down, to land' vs. *in-*, *sümük* 'bone' vs. *kemik*). Turkish *düş-* means 'to fall'; *sümük* means 'mucus.' The vocabulary has preserved numerous elements of Persian and Arabic–Persian origin that have been abandoned in Turkish as a result of the puristic language reforms, including *lüγet* 'dictionary' (Turkish *sözlük*), *müellim* 'teacher' (*öğretmen*), and *pul* 'money' (*para*).

Since the 19th century, Russian loanwords, particularly technical terms, have entered the northern Azerbaijanian varieties (*zavod* 'factory' (Turkish *fabrika*), *fevral* 'February' (Turkish *şubat*), *stul* 'chair' (Turkish *sandalye*), and *galstuk* 'necktie' (Turkish *kravat*)). The southern varieties exhibit many loans from Persian (e.g., *miz* 'table' and *ruzname* 'newspaper' (the northern varieties have *stol* and *gezet*).

Dialects

The spoken language includes several dialects. They are mostly divided into three groups: northern dialects spoken in the Republic of Azerbaijan, southern dialects in northwestern Iran, and East Anatolian dialects. Though these dialects differ a great deal from each other, they are mostly mutually intelligible. Among the northern dialects, there is a western subgroup in the central part of the Republic (including Genje, Shusha, Kazak, Karabagh, and Ayrum). Dialects of an eastern subgroup are spoken on the shore of the Caspian Sea, in Derbent, Kuba, Shemakha/Shamakhi, Baku, Sal'jany, Mughan, and Lenkoran, for example. The standard language is based on the urban dialect of the capital Baku. Dialects spoken in the northern parts of the Republic include Zakataly, Nukha, and Kutkashen. Dialects spoken in the southern parts of the republic include those of Nakhchevan and Ordubad.

The dialects of Iran include those of Tebriz, Urmia, Qūščī, Xoy, Marāγa, Marand, 'Oryān Tepe, Torkmānčay, Ardabīl, Sarāb, Meyāna, and the exclave Galūgāh. The dialect of the Karapapakh 'Black Caps' was spoken between the upper Kura

and Arpachay Rivers, on the boundary between Armenia and Georgia, and in Persian Azerbaijan near Lake Urmiya. Some dialects are spoken in Khorasan, including Loṭfābād and Daragaz.

B

Babylonian Grammatical Texts

G B Gragg, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Background: Writing, Lists, and Lexicography

What is, and undoubtedly will remain, the oldest attested tradition of grammatical analysis comes to us from cuneiform texts on clay tablets drawn up in the scribal schools of southern Mesopotamia. The tradition begins in the Old Babylonian Period (first half of 2nd millennium B.C.E.) with a corpus collectively known as the Old Babylonian Grammatical Texts (OBGT), assembled and published by scholars at the Oriental Institute of the University of Chicago in 1956, in the context of a series, Materials for the Sumerian Dictionary (MSL), whose 17-plus volumes make available the entire corpus of Sumerian school texts. The tradition continues, with important transformations and developments, through the Middle Babylonian Grammatical Texts (MBGT) and Neo-Babylonian Grammatical Texts (NBGT), down to the final stages of the use of cuneiform in the Seleucid period. Eighteen OBGT and nine NBGT texts are published in MSL 4, with a substantial critical-interpretative introduction by Thorkild Jacobsen; three MBGT texts are available in MSL Supplementary Series 1.

The grammatical tradition is, from the beginning, bilingual, consisting of long and often intricately structured parallel lists of words, phrases, and morphemes in Sumerian and Akkadian – invariably Sumerian in the left-hand column and Akkadian in the right. The obvious originating factor behind this genre of texts was the need on the part of Akkadian-speaking scribes to acquire the reading and writing knowledge of Sumerian, essential for advancement in the cultural and economic spheres (in the earlier stages), as well as the cultural and religious spheres (at all stages). But in this genre, as in the lexical, initial practical preoccupations often were overtaken by a drive to systematicity, symmetry, and formal completeness, which led to the creation of artificial forms, not attested in texts, to fill in gaps and unoccupied slots in the paradigms.

It is impossible to document exactly when grammar joined the curriculum of Mesopotamian schools, but the textual record shows that already at the earliest stages of writing at the end of the 4th millennium B.C.E., a certain portion of the cuneiform corpus is devoted to the sign lists and school exercises necessary for the transmission of knowledge about the writing system itself. At first these lists were monolingual Sumerian and, already at the beginning, developed quickly from simple lists of signs to topically arranged exhaustive enumerations of designations for flora, fauna, and artifacts. At the same time, an increasingly complex economy stimulated the development of elaborate, multicolumn hierarchical document formats with totals, subtables, subtotals, and summaries, to record increasingly complex transactions and inventories. In the meantime, very early in the development of the cuneiform writing system and perhaps nearly at its origins, the population of southern Mesopotamia was increasingly shifting toward Akkadian as its first language – including, as is shown by their proper names, the population of scribes and scribal students. This led, on the one hand, to an adaptation of the cuneiform writing system for Akkadian in the course of the 3rd millennium B.C.E. and, by the end of the millennium, to the addition of Akkadian columns to the monolingual school texts. The earliest of these simply provided Akkadian translations for the topically arranged inventories of words/things – the series called, from its *incipit*, Har-ra (= MSL 5–11). However this expansion allowed new genres of lexical texts to appear: lists in which the first column gives, in a reduced syllabary, a representation of the pronunciation value of the sign in the second column (to which still another column with a sign name might be added), with or without a final column with an Akkadian translation (MSL 2–3, 14); lists with synonyms or near synonyms in the two languages, thus nuancing the massive topical lists in the direction of a kind of thesaurus (see MSL 17); lists giving Sumerian equivalents, always in

the left-most column, of Akkadian words that share the same lexical root, thus in effect an Akkadian-Sumerian dictionary organized by roots (MSL 16); and lists giving supposedly useful phrases in the two languages for drawing up legal documents (MSL 1) or administrating agricultural or other economic units.

From Word Lists to Paradigms

It is only a short step from inventories of legal boilerplate to phrase lists illustrating the morphological and syntactic patterns of the language as such, thus the series from an OBGT in Table 1. Note here that the homophonous first- and second-person forms in Sumerian are differentiated in Akkadian and that Akkadian, which has a gender distinction in the second- and third-person pronouns, just uses the masculine form to translate the genderless corresponding forms in Sumerian.

It is an even closer step to abstract from such rudimentary phrases actual paradigms of the relevant parts of speech, as in OBGT I in Table 2. (Additional lines, not rendered here, give Sumerian variant orthographies and/or word forms corresponding to the simple Akkadian pronouns.) The other entries in this part of the text shows the plural forms of the pronouns in the two languages, first in the simple nominative form, then in combination with various enclitics, prepositions/postpositions, and finally verbal contexts. Note the familiar order of persons (1, 2, 3) consistently observed in all parts of this paradigm, as opposed to the variant orders we will see later in the verbal paradigms.

Table 1 OBGT phrase lists

OBGT line number	*Sumerian*	*Akkadian*
1.	dubsar-me-en scribe-COP-1.SING 'I am a scribe'	ṭupšarum anāku scribe PRO.1.SING 'I am a scribe'
2.	dubsar-me-en scribe-COP-2.SING 'you are a scribe'	ṭupšarum atta scribe PRO.2.MASC.SING 'you are a scribe'
3.	lú-e dubsar-a man-PROX scribe- COP.3.SING 'he (near) is a scribe'	annûm ṭupšarum this.3.MASC.SING scribe 'this one is a scribe'
4.	lú-ri dubsar-a man-far scribe- COP.3.SING 'he (far) is a scribe'	ullum ṭupšarum that.3.MASC.SING scribe 'that one is a scribe'

It is in the verb paradigms that the true complexity of the grammatical texts can be seen, particularly in five longer texts, each of which is devoted to the paradigm of a single important verb: OBGT VI *ŋar* = *šakānum* 'set'; OBGT VII *du*/*ŋen* = *alākum* 'go'; OBGT VIII *kas*$_4$ + *dug*$_4$ = *lasāmum* 'run'; OBGT IX *sá* + *dug*$_4$ = *kašādum* 'reach'; and OBGT X *gub* = *uzzuzum* 'stand.' Note that, in addition to dealing with more or less homologous inflectional categories of modality and subject and object PNG (person-number-gender), these paradigms also tackle Sumerian verbal categories that are entirely foreign to Akkadian, or at least to its inherited Semitic morphological grid: an aspectual distinction between durative and punctual, which is pivotal for Sumerian verb morphology and which in the verb 'go' is suppletive both for a singular and plural subject (*du* 'go.DURATIVE.SING' vs. *sub* 'go.DURATIVE.PL' vs. *ŋen* 'go.PUNCTUAL. SING' vs. *su* 'go.PUNCTUAL.PL'); a category of compound verb involving an incorporated nominal constituent in the 'reach' and 'run' paradigms; an m-series category of 'orientation to speaker/speech-situation', for which Akkadian seems to have developed a special first-person dative suffix (termed ventive); and, paired with the last category in this text, Sumerian forms prefixed with an opposing b-series, for which the Akkadian column consistently uses verbal forms in a passive-reflexive-derived stem with infix *–t-*.

The structure of the long (324 lines, of which 307 are preserved) 'go' paradigm is particularly complex and instructive. Lines 1–95 give, for a singular subject, first the modal forms (lines 1–30, with order of persons: 2 = imperative, 1 = cohortative, 3 = optative) and then the nonmodal forms (with order of persons: 3, 1, 2), durative (lines 31–67) and punctual (lines 68–95). Within each of these three major sections, verb forms are given (in terms of the Akkadian translation) in the ventive and nonventive, with and without *-t-* infix, and with and without singular object suffixes. Lines 96–190 then repeat this structure for a plural subject. Lines 191–246 repeat the whole structure of 1–190 with object pronouns of

Table 2 Pronoun paradigm

OBGT I line number	*Sumerian*	*Akkadian*
373–5	menden PRO.1.PL 'we'	nīnu PRO.1.PL 'we'
376–8	menzen PRO.2.PL 'you'	attunu PRO.2.MASC.PL 'you'
379–84	enene PRO.3.PL 'they'	šunu PRO.3.MASC.PL 'they (MASC)'

the first- and second-person plural (separable in Akkadian and given with a number of subtle morpho-semantic distinctions); lines 247–324 go over the same structure with object pronouns of the third-person plural. The excerpt in Table 3 gives, for the most basic forms, an idea of what is involved in this text.

The Last Stage: Morpheme Lists and Technical Terms

By the period of the NBGT, a number of which come from the famous library of Ashurbanipal in Nineveh, living contact with Sumerian was a millennium or more in the past. A few of the grammatical texts from this period repeat some of the full pronominal and verbal forms of the earlier texts but only in apparently scattered excerpts. For the most part, the NBGT consist of long lists of single signs and sign sequences, most of which represent classes of verb prefixes (occasionally suffixes) and prefix sequences, taken from the complex prefix chains that characterize Sumerian verb morphology. Note that because the cuneiform writing system is limited to the representation of syllables, prefixes consisting of a single consonant could not be directly represented. However, occasional sequences such as NBGT I lines 47–50, in which the Sumerian column has successively *un*, *an*, *in*, and *en* and only the first line is glossed in the Akkadian as 'I, full, prefix, infix,' may be an attempt to convey the notion of a prefix/infix *–n-* preceded by any vowel.

As in the passage just noted, the occasional glosses in the Akkadian columns are for the most part pronominal, but, much more interesting, they are frequently accompanied by technical grammatical terms describing the function and form assigned to the Sumerian affixes. The structure and rationale of these texts is far from clear, and the meaning of many of the terms is uncertain or unknown, but they clearly represent the end stage of a long tradition of analysis and teaching of Sumerian and must be counted among the earliest attempts to elaborate a technical linguistic terminology. A list and analysis of a number of these is given by Civil (1994): 'superior' (= prefix), 'middle' (= infix), 'inferior' (= suffix), 'of one' (= singular), 'of many' (= plural), 'quick' (= punctual), 'fat, slow' (= durative), 'empty' (= vocalic affix), 'full' (= vowel + consonant affix), 'complete' (= perfect?), 'leading' (= movement toward speaker?), 'which makes turn around' (= pronominal affix?), 'additional' (= ?), and 'late' (= ?).

Conclusion

Although we possess only the bare bones of the Mesopotamian grammatical tradition, a fossil remnant, as it were, of a living tradition of linguistic analysis, what we have is sufficient to show how, faced with a situation of rich language diversity and complex linguistic interaction, scholars responded by elaborating subtle and even elegant structures whose interpretation can fascinate their successors thousands of years later.

Back-Formation

F Katamba, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Normally word formation involves the addition of elements to an existing base. This may take a variety of forms. A common method is the attachment of inflectional or derivational affixes, shown in **Table 1**.

Another common technique is compounding. Existing bases, which may be fully fledged words, may be combined to create a new word. This is illustrated in **Table 2**.

Occasionally, words are formed by *back-formation*. When this happens, a new word is created by removing a real affix or a chunk of the word that is re-analyzed as an affix (Adams, 1973, 2001; Huddleston, 1984; Quirk *et al*., 1985; Huddleston and Pullum, 2002). Consider the examples in **Table 3**.

The words in **Table 3** were created by analogy to the words like *writer*, *governor*. The ending – pronounced ə (or ɚ in rhotic dialects) and spelled *-er, -or, -ar* – is interpreted as the agentive suffix meaning "someone who does x," which derives nouns from the corresponding verbs. Since the words in the left-hand column are nouns, it was wrongly presumed that there must be an unsuffixed verb base from which they must have been derived, and speakers proceeded to recover it.

The story of the word *beg* is instructive. According to Adams (1973), the verb *beg* was formed by analogy to *sing* (verb) and *singer* (noun), *write* (verb) and *writer* (noun). Speakers misinterpreted the *-ar* as an agentive suffix, although the apparent *-ar* suffix is unrelated to the agentive morpheme. The *Oxford English dictionary* (*OED*) shows *beggar* to be descended from medieval Latin *beghardus;* Old French *bégard*. This was a lay brotherhood that arose in the Low Countries in the 13th century, many of whose members were simply idle, vagrant mendicants.

Back-formation tends to be sporadic and unsystematic. It is not possible to predict when and where it will happen. However, some morphological contexts seem more favorable to it than others. For instance, nouns ending in *-ion* are quite susceptible to having *-ion* removed to yield a verb; see **Table 4**.

By contrast, certain other suffixes – such as *-ity*, as in *electricity* and *divinity* – do not lend themselves so readily to back-formation (cf.**ident* and **tenac* from *identity* and *tenacity)*.

Acceptability of Back-Formations

Many new back-formations are not well received and occasionally attract a considerable amount of negative comment. The morphological misanalysis that motivates them is viewed by some as a sure sign of a poor command of the language. That is true of the back-formation *cohabitate*, from *cohabitation*, which is used instead of the established word *cohabit*, or *orientate*, from *orientation*, which some use instead of the more established word *orient*.

At least in part, the problem here seems to be that the new *cohabitate* and *orientate* look odd, but in time everyone might get used to them. However, this

Back-Formation

F Katamba, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Normally word formation involves the addition of elements to an existing base. This may take a variety of forms. A common method is the attachment of inflectional or derivational affixes, shown in Table 1.

Another common technique is compounding. Existing bases, which may be fully fledged words, may be combined to create a new word. This is illustrated in Table 2.

Occasionally, words are formed by *back-formation*. When this happens, a new word is created by removing a real affix or a chunk of the word that is re-analyzed as an affix (Adams, 1973, 2001; Huddleston, 1984; Quirk *et al*., 1985; Huddleston and Pullum, 2002). Consider the examples in Table 3.

The words in Table 3 were created by analogy to the words like *writer*, *governor*. The ending – pronounced ə (or ɚ in rhotic dialects) and spelled *-er, -or, -ar* – is interpreted as the agentive suffix meaning "someone who does x," which derives nouns from the corresponding verbs. Since the words in the left-hand column are nouns, it was wrongly presumed that there must be an unsuffixed verb base from which they must have been derived, and speakers proceeded to recover it.

The story of the word *beg* is instructive. According to Adams (1973), the verb *beg* was formed by analogy to *sing* (verb) and *singer* (noun), *write* (verb) and *writer* (noun). Speakers misinterpreted the *-ar* as an agentive suffix, although the apparent *-ar* suffix is unrelated to the agentive morpheme. The *Oxford English dictionary* (*OED*) shows *beggar* to be descended from medieval Latin *beghardus;* Old French *bégard*. This was a lay brotherhood that arose in the Low Countries in the 13th century, many of whose members were simply idle, vagrant mendicants.

Back-formation tends to be sporadic and unsystematic. It is not possible to predict when and where it will happen. However, some morphological contexts seem more favorable to it than others. For instance, nouns ending in *-ion* are quite susceptible to having *-ion* removed to yield a verb; see Table 4.

By contrast, certain other suffixes – such as *-ity*, as in *electricity* and *divinity* – do not lend themselves so readily to back-formation (cf.**ident* and **tenac* from *identity* and *tenacity)*.

Acceptability of Back-Formations

Many new back-formations are not well received and occasionally attract a considerable amount of negative comment. The morphological misanalysis that motivates them is viewed by some as a sure sign of a poor command of the language. That is true of the back-formation *cohabitate*, from *cohabitation*, which is used instead of the established word *cohabit*, or *orientate*, from *orientation*, which some use instead of the more established word *orient*.

At least in part, the problem here seems to be that the new *cohabitate* and *orientate* look odd, but in time everyone might get used to them. However, this

Table 1

Inflection	*Derivation*	
talks	governor	misgovern
talked	government	ex-governor
talking	governable	ungovernable

Table 2

Noun	+ *Noun*	*Compound Noun*
desk	top	desktop
rail	way	railway
fire	fighter	firefighter

is not certain. Some back-formations of long standing, like *aggress* and *intuit* (dating from 1575 and 1776 respectively, according to the *OED*), have not yet gained common currency. Many others have won acceptance. *Resurrect* and *separate* do not seem to us in any way odd and attract no comment. Resistance to back-formations seems strongest in cases where the new word competes with a synonymous established word that shares the same root, as in the cases of *cohabitate* and *orientate*.

Note, however, that some back-formations are not warmly embraced even when they are established. The reluctance to embrace them manifests itself in the somewhat restricted range of verbal inflections that they are allowed to take (cf. Quirk *et al*., 1985; Huddleston and Pullum, 2002). For instance, many who will accept the back-formation *self-destruct* from *self-destruction* do not tolerate the word if it is given the *-ed* inflection (**he self-destructed*). Likewise, while *sightsee*, *housekeep*, and *daydream* are acceptable, none of the sentences here, with the back-formation of these in the past tense, would be judged well formed:

a. **Jane sightsaw.*
b. **We housekept.*
c. **I daydreamed all afternoon.*

Table 3

Original word	*New word*
editor	edit
inspector	inspect
sculptor	sculpt
juggler	juggle
swindler	swindle
peddler	peddle
burglar	burgle
beggar	beg
scavenger	scavenge
swashbuckler	swashbuckle (> swashbuckling)

Table 4

intuit	intuition
resurrect	resurrection
donate	donation
orientate	orientation
emote	emotion
televise	television
separate	separation
administrate	administration
liaise	liaison
agress	aggression

Many back-formations live at the margins of grammar, where experimentation may result in jocular effects. When *gruntled* is formed from *disgruntled*, and *couth* from *uncouth*, the effect is normally intended to be humorous. Where the speaker or writer has no humorous intent, others may still ridicule their use of an odd-sounding back-formation. That is what happened when an officer of the law used the back-formation *allegate*, which is derived from *allegation*, instead of the established word *allege*:

> . . . an officer of a Florida court stated that a plaintiff had 'allegated' something. He then referred to the plaintiff as 'the allegator,' summoning up the vision, in a state in which alligators are common, of a reptile-plaintiff (Block, 2004).

Back-Formations from Compounds

Back-formations are a highly productive method of creating denominal verb compounds. The back-formations created in this fashion fall into three broad categories (Marchand, 1969; Adams, 1973, 2001; Huddleston, 1984; Quirk *et al*., 1985; Huddleston and Pullum, 2002). In one type, the source compound ends in *-er* or *-ing* and the semantic role of the first noun is like that of a patient argument of the verb in a normal sentence; see Table 5.

Thus, a *stage manager* is a person who *manages a stage*, a *word processor* is a device that is used to *process words*, and so on. The back-formation removes the ending from the entire noun compound to yield the compound verb, but the argument structure remains unchanged.

In the second type, which is exemplified in Table 6, the syntactic construction that is the source of the compound verb is verb + PP – e.g., *spring-cleaning* is derived from *cleaning during spring*, *daydreaming* is from *dreaming during the day*, and so on.

Table 5

bookkeeper	book-keep
headhunter	headhunt
gate-crasher	gate-crash
air conditioner	air-condition
bargain hunt	bargain hunt
babysitter	babysit
housekeeper	housekeep
stage manager	stage-manage
firefighter	firefight
word processor	word process
typewrite	typewrite
lipreading	lip-read
house hunting	house hunt

Table 6

spring-cleaning	spring-clean
daydreaming	daydream
sleepwalking	sleepwalk
chain-smoking	chain-smoke

Table 7 Hypocoristics

Japanese	Akira	Aki-tyan
(Mester, 1990)	Midori	Mii-tyan

Removal of the ending, again, does not affect the semantic relation between the first and second parts.

The third type changes a compound whose second constituent is a participial adjective into a verbal compound whose first constituent is some sort of adjunct. Examples of this include the verb *spoon-feed* from *spoon-fed* (Marchand, 1969) and the verbs *handpick* and *fast-freeze* from *handpicked* and *fast-frozen*.

Hypocorism

This type of back-formation is not motivated by analogy. It involves the truncation of a longer word without the excuse of there being an affix that is removed. Numerous languages have hypocoristic forms of nouns. They are especially prevalent in the familiar versions of personal names. Typically, hypocoristics are minimal words that have two syllables or two moras. In French, for example, *Isabelle* is reduced to *Iza*, *Zabel*, or *Zabe*.

Japanese also has hypocoristic versions of personal names. As seen in Table 7, they too have a bimoraic base, to which is added the familiar ending *-tyan*. Examples of hypocorism in English are given in Table 8.

In English such truncation is also common and it is accompanied by the attachment of a *-y* or *-ie* suffix.

This process is also applicable to common nouns and is especially popular in Australian English; see Table 9.

The last example in Table 9 shows that the truncated word is not always a term of endearment.

Table 8

Jennifer	Jenny
Amanda	Mandy
Anthony	Tony
Margaret	Maggie
Elizabeth	Betty, Bessie, etc.

Table 9

barbecue	barbie
breakfast	brekky
Australian	Aussie
postman	postie
mosquito	mozzie

Back-Formation in Inflection

So far, we have only dealt with back-formation in derivational morphology. In rare cases, back-formation is also attested in inflectional morphology. For instance, a few English nouns ending in *-s* that were originally singular in number were incorrectly analyzed as plural and a singular form lacking the -s was created by back-formation.

Two famous examples are *cherry* and *pea*. The *OED* shows that *cherry* is a back-formation from Old Northern French *cherise*, which was mistaken for a plural. Similarly, *pea* is a back-formation from the word originally spelled *pease* or *peas*, which was the word for the round seed of the plant whose botanical name is *Pisum sativum*, which was a non-countable mass noun. The *-s* was taken off to create the basic singular form, *pea*.

Though not insignificant, back-formation is not a major technique for forming words in English. It is far less important than conversion, whereby a word is derived without an overt change in form (e.g., *jump* [verb] > *jump* [noun]); affixation, whereby a word is formed by adding a prefix or suffix (e.g., *dance* [verb] > *dancer* [noun]); or compounding (e.g., *hot* [adjective] + *spot* [noun] > *hot spot* [noun]). A statistical analysis of the *OED* shows that between 1880 and 1882, only 2.6% of new words were shortenings; 18.5% were compounds; prefixation accounted for 12.4%, and suffixation was responsible for a staggering 47.4% (Bauer, 1994).

Bacon, Francis, Lord Verulam (1561–1626)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Francis Bacon was a foremost thinker in philosophy and scientific methodology at the twilight of Renaissance and the new rationalist order. His ambition was to reform the advancement in scientific knowledge starting with a criticism of scholasticism and Aristotelianism. His reform also had a social character and included the reclassification of sciences. Bacon's thoughts on language, a portion of his theories, are relevant to language sciences and history of ideas in linguistics.

In *Advancement of learning, arts intellectual* (1605), Bacon outlines the role of language in the preservation and transmission of human knowledge and discusses the relation between language and thought, language and linguistic and non-linguistic communication, oral/written language including writing systems, arbitrariness and the 'science of grammar.' Whereas a 'philosophical' grammar studies 'the power and nature of words as they are the footsteps and prints of reason,' the analogy between words and reason, reality, a 'popular' or 'literary' grammar encourages 'speedy and perfect' learning of languages, for 'the intercourse of speech and understanding of authors.' On the basis of the analogy between words and reason in the philosophical grammar, Bacon construes the conceptual framework for the investigation of languages as the sources of knowledge about peoples' customs and beliefs, manifested in 19th and 20th century theories of language and culture. The *Advancement of learning* also introduces Bacon's thoughts on ciphers and hidden languages 'the art of ciphering and deciphering.' He argues for a hierarchical system of 'real characters' to express basic 'things and notions.'

In *Novum Organum* (1620), he postulated a replacement for deductive reasoning by his new inductive or scientific reasoning. Significant conceptual changes in scientific thinking and an intellectual revolution ensued. His intellectual legacy exerted broad influence during his lifetime and subsequently gained much more prestige. Language underpinned the search for a new method to gain knowledge of nature. Bacon elaborates on the pervading theme of the deceptiveness of language, the most common reference in any work on Bacon, in the memorable discussion of the four 'idols of the mind' and particularly 'idols of the market-place.' Jointly, they ushered a series of works on artificial languages in the 17th century. Since then, a tradition of postulating philosophical theories on the deceptive character of language has been established among the analytical philosophers in Great Britain. Equally important is the critique of logic and rhetoric. Bacon viewed logic as the rules of thinking. Only recently linguists have begun to turn their attention to Rhetoric to study communication, pragmatics and semantics.

Although Bacon was aware that a theory of signs was important; it was to remain a *desideratum*. The 18th and 19th century investigation and comparison of the world languages was arguably based on his scientific principles. Francis Bacon's own use of language has been itself a pertinent research object.

His reform also had a social character and included the reclassification of sciences. Bacon's thoughts on language, a portion of his theories, are relevant to language sciences and history of ideas in linguistics.

In *Advancement of learning, arts intellectual* (1605), Bacon outlines the role of language in the preservation and transmission of human knowledge and discusses the relation between language and thought, language and linguistic and non-linguistic communication, oral/written language including writing systems, arbitrariness and the 'science of grammar.' Whereas a 'philosophical' grammar studies 'the power and nature of words as they are the footsteps and prints of reason,' the analogy between words and reason, reality, a 'popular' or 'literary' grammar encourages 'speedy and perfect' learning of languages, for 'the intercourse of speech and understanding of authors.' On the basis of the analogy between words and reason in the philosophical grammar, Bacon construes the conceptual framework for the investigation of languages as the sources of knowledge about peoples' customs and beliefs, manifested in 19th and 20th century theories of language and culture. The *Advancement of learning* also introduces Bacon's thoughts on ciphers and hidden languages 'the art of ciphering and deciphering.' He argues for a hierarchical system of 'real characters' to express basic 'things and notions.'

In *Novum Organum* (1620), he postulated a replacement for deductive reasoning by his new inductive or scientific reasoning. Significant conceptual changes in scientific thinking and an intellectual revolution ensued. His intellectual legacy exerted broad influence during his lifetime and subsequently gained much more prestige. Language underpinned the search for a new method to gain knowledge of nature. Bacon elaborates on the pervading theme of the deceptiveness of language, the most common reference in any work on Bacon, in the memorable discussion of the four 'idols of the mind' and particularly 'idols of the market-place.' Jointly, they ushered a series of works on artificial languages in the 17th century. Since then, a tradition of postulating philosophical theories on the deceptive character of language has been established among the analytical philosophers in Great Britain. Equally important is the critique of logic and rhetoric. Bacon viewed logic as the rules of thinking. Only recently linguists have begun to turn their attention to Rhetoric to study communication, pragmatics and semantics.

Although Bacon was aware that a theory of signs was important; it was to remain a *desideratum*. The 18th and 19th century investigation and comparison of the world languages was arguably based on his scientific principles. Francis Bacon's own use of language has been itself a pertinent research object.

Bacon, Roger (c. 1214–1292/94)

M Thomas, Boston College, Chestnut Hill, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Little is known about the life of the 13th-century English friar Roger Bacon. He was probably born in Somerset. He studied and subsequently lectured at both Oxford and Paris, and entered the Franciscan order in his thirties or forties. We do know that Bacon wrote voluminously on many topics – mathematics, philosophy, optics, geography, alchemy, astronomy, and languages – and that he had a fiercely independent and critical temperament (Little, 1972). He championed an experimental approach to knowledge of the world, in opposition to the metaphysical orientation of medieval scholasticism. In the field of language, Bacon was unusual in his day in arguing for the importance of study of Greek, Hebrew, and Arabic, and in his interest in cross-linguistic comparison and dialectal variation.

Bacon achieved notoriety in his lifetime for his unconventional intellectual interests and his attacks on other scholars. But his own scholarship sometimes lacks objectivity and depth. Easton (1952: 33) wrote: "Bacon can give a masterpiece of brilliant exposition of a difficult theory, then follow it elsewhere with absurd and puerile non-sequiturs; he can produce a violent polemic and then ruin it with a piece of contradictory evidence which he does not see will vitiate the whole."

This difficult and original scholar has, implausibly, become identified as having anticipated modern generative grammar's concept of Universal Grammar. At issue is a single passage from one of Bacon's minor

He studied and subsequently lectured at both Oxford and Paris, and entered the Franciscan order in his thirties or forties. We do know that Bacon wrote voluminously on many topics – mathematics, philosophy, optics, geography, alchemy, astronomy, and languages – and that he had a fiercely independent and critical temperament (Little, 1972). He championed an experimental approach to knowledge of the world, in opposition to the metaphysical orientation of medieval scholasticism. In the field of language, Bacon was unusual in his day in arguing for the importance of study of Greek, Hebrew, and Arabic, and in his interest in cross-linguistic comparison and dialectal variation.

Bacon achieved notoriety in his lifetime for his unconventional intellectual interests and his attacks on other scholars. But his own scholarship sometimes lacks objectivity and depth. Easton (1952: 33) wrote: "Bacon can give a masterpiece of brilliant exposition of a difficult theory, then follow it elsewhere with absurd and puerile non-sequiturs; he can produce a violent polemic and then ruin it with a piece of contradictory evidence which he does not see will vitiate the whole."

This difficult and original scholar has, implausibly, become identified as having anticipated modern generative grammar's concept of Universal Grammar. At issue is a single passage from one of Bacon's minor

works, his *Greek grammar* (eds. Nolan and Hirsch, 1902: 27), in which he asserted that "the substance of grammar is one and the same in all languages, despite variation in its accidents." Thomas (2002) analyzes more than 50 citations of this passage. Many follow Chomsky's (1966: 105) use of it to depict medieval speculative grammar, which he connects to 'Cartesian linguistics' and hence to generative grammar. Hovdhaugen (1990), however, distinguishes Bacon's approach from the speculative grammarians' assumptions about the unity of language, thought, and reality. Bourgain (1986) and Rosier (1984) add other evidence that Bacon's reputation as a precursor of modern Universal Grammar is unwarranted. Notwithstanding the famous 'one and the same' passage, Bacon's real contribution to linguistics lies in his promotion of foreign language study.

Bactrian

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Bactrian was the local Iranian language of the Greco-Bactrian (or Kushana) kingdom in northern Afghanistan, founded by soldiers of Alexander the Great. The language is known from coins, a few stone and wall inscriptions (private and royal, the earliest from the 2nd century), and a small number of manuscript fragments from Turfan, as well as a large number of economic and legal documents, mainly on parchment, from northwestern Afghanistan dated between 342 and 781 A.D. It shares features with both Parthian, its western neighbor, and Chorasmian and Sogdian, its northern neighbors.

Bactrian is the only Iranian language written in Greek script. One letter was added to write *š* (similar in form to the Old Norse letter *þ*, which is commonly used to transcribe it, e.g., *κανηþκο* = *kanēško*). The letter <o> spelled *u* between consonants, *h* after vowels, and was probably not pronounced in final, but served as an end-of-word marker. This final *-o* often becomes *-a* before enclitics (e.g., *abo* 'to,' but *aba-fago* 'to you'; *oto* 'and,' but *ota-kaldo* 'and when'). Other final vowels are rare (except in the oldest inscriptions), and no words end in consonants. The consonants <s> and <z> may be ambivalent, as they correspond to both <s> and <z> and palatal <ś> and <ź> in the text in Manichean script.

The inscriptions are written in capital letters (without spaces between the words), while secular documents are written in a cursive ductus, in which several letters are sometimes identical. There are several Manichean or Buddhist texts in Greek cursive and one manuscript leaf in the Manichean script.

Gender (MASC-FEM) is distinguished in the definite article and in some adjectives (e.g., **torosaggo* [tursāng] 'Turkish,' FEM *torosanzo* [tursānz]) and in the perfect participles (e.g., *nabixt-igo* [nabixt-ig] MASC 'written,' FEM *nabixt-iso* [nabixt-is]). In the earliest inscriptions, there is still a two-case (direct and oblique) system of the noun, which in the documents survives mainly in pronouns. Thus, in the inscriptions we find SING. *i bago* 'the god.SING. DIR' and PL. *i bage* 'the god.PL.DIR' as subject, but *bag-ano* 'god-PL.OBL' as genitive; *kanēško* 'Kanishka. SING.DIR' as subject, but *kanēški/kanēške* 'Kanishka. SING.OBL' as agent and genitive.

Bactrian

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Bactrian was the local Iranian language of the Greco-Bactrian (or Kushana) kingdom in northern Afghanistan, founded by soldiers of Alexander the Great. The language is known from coins, a few stone and wall inscriptions (private and royal, the earliest from the 2nd century), and a small number of manuscript fragments from Turfan, as well as a large number of economic and legal documents, mainly on parchment, from northwestern Afghanistan dated between 342 and 781 A.D. It shares features with both Parthian, its western neighbor, and Chorasmian and Sogdian, its northern neighbors.

Bactrian is the only Iranian language written in Greek script. One letter was added to write *š* (similar in form to the Old Norse letter *þ*, which is commonly used to transcribe it, e.g., *κανηþκο* = *kanēško*). The letter <o> spelled *u* between consonants, *h* after vowels, and was probably not pronounced in final, but served as an end-of-word marker. This final *-o* often becomes *-a* before enclitics (e.g., *abo* 'to,' but *aba-fago* 'to you'; *oto* 'and,' but *ota-kaldo* 'and when'). Other final vowels are rare (except in the oldest inscriptions), and no words end in consonants. The consonants <s> and <z> may be ambivalent, as they correspond to both <s> and <z> and palatal <ś> and <ź> in the text in Manichean script.

The inscriptions are written in capital letters (without spaces between the words), while secular documents are written in a cursive ductus, in which several letters are sometimes identical. There are several Manichean or Buddhist texts in Greek cursive and one manuscript leaf in the Manichean script.

Gender (MASC-FEM) is distinguished in the definite article and in some adjectives (e.g., **torosaggo* [tursāng] 'Turkish,' FEM *torosanzo* [tursānz]) and in the perfect participles (e.g., *nabixt-igo* [nabixt-ig] MASC 'written,' FEM *nabixt-iso* [nabixt-is]). In the earliest inscriptions, there is still a two-case (direct and oblique) system of the noun, which in the documents survives mainly in pronouns. Thus, in the inscriptions we find SING. *i bago* 'the god.SING. DIR' and PL. *i bage* 'the god.PL.DIR' as subject, but *bag-ano* 'god-PL.OBL' as genitive; *kanēško* 'Kanishka. SING.DIR' as subject, but *kanēški/kanēške* 'Kanishka. SING.OBL' as agent and genitive.

A definite animate direct object is indicated by the preposition *abo* 'to.'

The verbal system is of the common Iranian type. There are three stems: present, past, and perfect (perfect participle = past stem + suffix *-igo*, FEM *-iso*; e.g., PRES *nabis-* 'write,' PAST *nabixt-*, PERF MASC *nabixt-igo*). Special features include modal forms formed from the indicative plus the original modal third singular ending.

optative: *ma froxoaš-ond-ēio* [fraxwaš-und-ēy]
lest leave-INDIC.3RD.PL-OPT.3RD.SING
'lest they abandon'

subjunctive: *boo-ado* [buw-ād]
become-SUBJ.3RD.SING
'(that) he shall become'

and

boo-ind-ado [buw-ind-ād]
become-INDIC.3RD.PL-SUBJ.3RD.SING
'(that) they shall become'

The perfect is formed with the old participle in **-aka-*

ot-ēia . . . pidgirbo fromado kirdi eim-oano bag-ano ki-di m-aska nibixt-ig-endi
and-he.OBL image ordered.PAST do.INF these-PL.OBL god-PL.OBL REL-PART the.OBL-above written-PERF.PART-COP.PRES.3RD.PL
'and he ordered images to be made of these gods which are written above'.

In the ergative construction, the relatively widespread phenomenon of letting verbs such as 'give' agree with the indirect object is found in Bactrian as well.

od-omo ladd-ēi iōgo zino
and-I.OBL give.PAST-be.2ND.SING one woman
'and I have given you a (certain) woman'

A feature unusual in Iranian is the preposed negation in past tenses.

ko-ado-mēno n-isto paralado
that-PARTICLE-we.OBL not-is.3RD.SING sold.PAST
'that we have not sold'

A typically Bactrian construction is that of the subjunctive or optative with the particle *-an* used to express future eventuality.

(1) *asid-ano oalo šatar-ano* [*šatar* < *šado* + *-tar*] *kald-ano abo to xoēo xoado lrogo oēn-ano*
but-PART there happy.COMP-COP.SUBJ.1ST.SING when-PART DO you lord self healthy see.PRES-SUBJ.1ST.SING
'but I shall be happier there when I see you myself healthy'

(2) *ot-ēio pido asagg-e iθo oilirdo at-ano abo ma lizo faro karano abo ma gao-ēio*
and.PART-he.OBL on stone-PL thus arrange.PAST so that-PART in DEF citadel for people water NEG lack-OPT.3RD.SING
'and on (it) he placed stones so that in this citadel water might not be lacking for the people'

The particle *-do* is commonly attached to initial conjunctions, as in *kal-do* 'when,' *aki-do* 'who,' and *asi-do* 'which'; the common form *oto* 'and' is from *odo* 'and' + *-do*.

Badawi, El-Said Muhamed (b. 1929)

Z Taha, The American University in Cairo, Cairo, Egypt

© 2006 Elsevier Ltd. All rights reserved.

El-Said Muhamed Badawi was born on July 5, 1929 in a small village in Sharqiyyah, Egypt. He is best known for two major works in the field of Arabic linguistics; his book entitled *On levels of contemporary Arabic in Egypt*, and his *Dictionary of Egyptian Arabic* (1986). In the former, he introduced a case of multidiglossia, as opposed to the earlier bilateral divisions introduced by Ferguson.

As the eldest of four children in the family, he was sent to study Arabic and Qur'anic studies at the Azhar-affiliated religious Institute of Al-Zaqaziq. After he graduated, he moved to Cairo where he studied at Dar Al-Ulum and got his B.A. degree with honors in Arabic language and literature, and Islamic studies in 1954. He then worked in the Cairo English School for four years as a teacher of Arabic and religion. It was there where he met a young Irish lady, Mary, and shortly after that they got married. He went to England to study for his M.A. in general linguistics on his own expense. He lived in England for 10 years, where he received both his M.A. and his Ph.D. from the University of London. He was granted a full scholarship to do his Ph.D. on phonetics and to carry out the field research for his thesis on the intonation of Riyadhi Arabic as spoken in Saudi Arabia.

Badawi was on loan from his home institution, once to the University of Umdurman in Sudan between 1966 and 1969, and the second time in Cairo at the American University in Cairo (AUC) in 1970. He finally resigned from Dar Al-Ulum and was granted tenure at AUC. Since that time, Badawi has continued to work at AUC in different capacities as a professor of Arabic and linguistics, and as a senior administrator. Since 1989, he has been working as the director of the Arabic Language Institute (ALI) and co-director of the Center for Arabic Study Abroad (CASA).

Since he set foot at AUC, Badawi has always tried to develop the Arabic language component at both the undergraduate and graduate levels. During his tenure, ALI has become an independent department where nonnative students have been studying Arabic at different levels of proficiency. He was the first to think of launching an M.A. program to qualify teachers of Arabic as a foreign language. The program started to offer academic degrees in 1978 under his directorship and has graduated about 90 students since then. He has also been working on promoting a B.A. degree in Arabic for nonnative speakers for the past six years. Badawi continues to teach graduate courses in Arabic Syntax, Phonetics of Arabic, Sociolinguistics, and Arabic Dialectology. His major research interest has been in dialects. Some of his publications received international recognition, such as *A comparative study of Egyptian Arabic* (1978), *Al-Kitab Al-Asasi* (1983), *Dictionary of Arab names* (1990), and *Modern written Arabic, a comprehensive grammar* (2004). He published many articles in local and international journals dealing with teaching Arabic as a foreign language and Arabic linguistics. Over the last four years, Badawi has been working with a group of linguists on compiling an Arabic–English dictionary of Qur'anic usage. The project is financed by the SOAS at the University of London.

The Bahá'í Faith is the religion of the followers of Bahá'u'lláh (1817–1892), which signifies in Arabic 'The Glory of God.' The faith first appeared in Persia (modern-day Iran) in a Shiite milieu, whence it may be considered to have sprung from an Islamic background in the same way as did Christianity from Judaism. Bahá'u'lláh, who was otherwise known as Mírzá Ḥusayn 'Alí, was of noble ancestry, and a lineal descendant of both Abraham and Zoroaster. The Bahá'í Faith sprang more immediately from what Bahá'ís regard as a precursor revelation, the Bábí Faith. The prophet-founder of the Bábí Faith, Siyyid 'Alí-Muḥammad (1819–1850), was also a Persian, and, as his designation of *Siyyid* indicated, a descendant of the Prophet Muḥammad. He assumed the title of The Báb, signifying in Arabic 'The Gate.' The Báb taught that the purpose of his mission was to herald a revelation far greater than his own, a prophecy which Bahá'u'lláh fulfilled when in 1863 he declared his mission in Baghdad, the occasion of the greatest of Bahá'í Festivals. Bahá'u'lláh appointed as successor his eldest son, 'Abdu'l-Bahá (1844–1921), who, with the Báb and Bahá'u'lláh, is the third of the three central figures of the Bahá'í Faith.

Bahá'ís believe that their religion is unique in the vastness and the authenticity of its scriptures, which, revealed in both Arabic and Persian and now rendered into most languages, comprise a substantial number of individual works only some of which, such as Bahá'u'lláh's *The hidden words*, *The book of certitude*, and the *Kitáb-i-Aqdas* (The most holy book), bear specific titles.

The fundamental teaching of the Bahá'í Faith is unity, whether of God, humanity, or religion. Bahá'u'lláh, who reaffirmed the oneness of God, taught further that all the great religions had proceeded from a single divine origin; all were fundamentally in agreement, and all had progressively expounded a single universal faith, albeit prescribing different social teachings to suit the needs of different ages. "The earth," he announced, "is but one country and mankind its citizens," while the destiny of all peoples was to live together in harmony within a single, equitable global polity. The supreme remedy for the ills afflicting the world was for humanity to unite in "one universal Cause, one common Faith," whose establishment should signal the fulfillment of the millennial expectations cherished by all religions, leading to the unfolding of universal peace based on justice, a civilization of unparalleled splendor, and the inauguration of a Golden Age in humanity's development on earth. It was this supernal vision that he, as the promised one of all ages, had been commissioned to realize.

By the terms of Bahá'u'lláh's Covenant, authority in the community passed to his eldest son 'Abdu'l-Bahá, thence to his great-grandson Shoghi Effendi, and is now vested in the Universal House of Justice, an elected council presiding over a hierarchy of similar bodies at national and local levels. These constitute the Bahá'í Administrative Order, the pattern of Bahá'u'lláh's new world order, and its ultimate safeguard against schism.

The Bahá'í World Centre in the northern reaches of the Holy Land has been the spiritual and administrative center of the Bahá'í Faith since Bahá'u'lláh was exiled there, in 1868, by the Ottoman government in collusion with the Persian government and the Persian and Turkish Muslim religious hierarchies. The burial places of the Báb on Mount Carmel in Haifa and of Bahá'u'lláh in Bahjí near Acre are the two holiest places on earth for Bahá'ís.

Bahamas: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of the Commonwealth of the Bahamas is English, with 296 000 speakers, existing in a Creole continuum with Bahamas Creole English. Bahamas creole English is reported to be very close to Sea Islands Creole English and Afro-Seminole Creole of the United States.

That the English of the Bahamas is reported to be more reminiscent of American varieties than of the Caribbean Englishes has historical reasons. From 1670 to 1720, the Bahamas and Carolina were a single colony. After the American Revolution, many American loyalists and their slaves emigrated to the Bahamas. Because the Bahamas were unsuited to the cultivation of sugar cane, the population remained mixed for much longer (*see* **Antigua and Barbuda: Language Situation** and **Barbados: Language Situation**). Some loyalists attempted cotton production on some of the southern islands. When the cotton failed, many were financially ruined and abandoned their plantations, leaving their slaves in virtual freedom. Thus, many of the southern islands apparently had almost exclusively African populations, in contrast to the situation in the north, where the population was more mixed. This relative isolation meant that their speech retained many Creole features that were losing ground in the north.

Significant minority languages are Haitian Creole French, spoken among Haitian immigrants, and English. There is a deaf population of 16 481 and two deaf institutions. There is a dictionary of Bahamas Creole English. Literacy is 95%.

A language now extinct in the Bahamas is Taino, an Arawakan language. Its original speakers were enslaved by the Spanish, who sent them to the then Spanish colony Santo Domingo on Hispaniola (which later became the Dominican Republic) where the community died. The remaining speakers of Taino now mainly live in the United States, Puerto Rico, and Cuba. Existing speakers in these countries estimate their language to be approximately 55% Taino and 45% Spanish.

Bahrain: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of Bahrain, an island state in the Persian Gulf, is Arabic. As in other Arab countries, the language situation in Bahrain is characterized by diglossia: Modern Standard Arabic (Arabic, Standard) is used in writing and for formal situations, and colloquial Gulf and Baharna Arabic are used in everyday speech. Of the 677 000-strong population of Bahrain, about a third (235 000) are nonnationals, and there are comparatively large communities of speakers of other varieties of Arabic, as well as of Persian (Farsi) and Urdu. The use of English is widespread in all domains of public life, reflecting the strong historical ties between Bahrain and Great Britain. The role of English has become even more important over the past two decades with the diversification of Bahrain's economy, which, after decreasing oil production, has been developing international banking and tourism sectors.

The public education system was established in 1919, and adult literacy in 2002 was 88.5%. Literacy of people from 15 to 24 years of age was even higher, 98.6%.

Bahrain's media publish in Arabic, but there are English language daily newspapers as well as an English channel on the local radio station run by the Bahrain Radio and Television Corporation.

Bakhtin, Mikhail Mikhailovich (1895–1975)

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Mikhail Milosevic Bakhtin was born in Orel, Russia, south of Moscow, on November 16, 1895. Coming of age in turbulent times, he attended Saint Petersburg University between 1916 and 1918, dividing his time between classics, literature, and philosophy, while maintaining a keen interest in language outside the classroom. During the 1920s Bakhtin came into contact with Voloshinov and Medvedev, two fellow intellectuals who shared his broad interests in language, politics, dialogue, and literature. Later known as the Bakhtin Circle, these young writers met regularly to discuss the philosophy of language until 1929, when Bakhtin was arrested, detained, and later exiled to Kustanai in 1930. After working as a bookkeeper on a collective farm, Bakhtin traveled to Saransk in 1936 to accept a position at the Mordovia Pedagogical Institute, where he taught Russian and world literature until his retirement in 1961. In 1940, Bakhtin submitted his dissertation, *Rabelais and the history of realism,* to the Institute of World Literature in Moscow, for which he was awarded the lesser degree of Candidate of Philological Sciences in 1952, rather than the doctorate. Although Bakhtin was a humble scholar who received little public recognition during his lifetime, his ideas have had an enormous, global impact on the philosophy and sociology of language. Bakhtin died in Moscow, Russia, on March 7, 1975.

Bakhtin is best known for his work on dialogue, a concept he continued to develop over the course of his career. For Bakhtin, dialogue was the central reality of language, a position partly inspired by the Greek philosopher Socrates, who stressed the emergent nature of truth in dialogic exchanges between opposing parties. In Bakhtin's estimation, the most productive exchanges occur between parties that enter into a discussion with contrasting points of view, allowing for change and diversity in society. Bakhtin hinted at this position in his first major publication, *Problems in Dostoevsky's poetics* (1929), in which he praised Dostoevsky for writing 'polyphonic' novels that represent the many competing voices found in every society. Because these voices resonate with larger systems of thought, such political orientations or even scientific worldviews, Bakhtin maintained that ideology, or perspective, is pervasive in everyday language use.

The political implications of dialogue are greatly expanded in Bakhtin's later writings. In *The dialogic imagination* (1981), he identified two major trends on the ideological plane. One tendency is toward homogeneity, where 'centripetal' forces seek to centralize the perspectives, discourses, or linguistic varieties found in society, reducing diversity and the possibility of change. Taken to an extreme, this monologic tendency leads to the death of dialogue, a fearful possibility that Bakhtin personally experienced under Stalin's regime. Fortunately, other 'centrifugal' forces are at work, destabilizing meaning by promoting diversity within society, whether as competing discourses or contrasting linguistic varieties. Here Bakhtin offered one of his most important concepts, that of 'heteroglossia,' where these competing centripetal and centrifugal forces enter into ongoing conflict, potentially sustaining internal diversity within a speech community, as separate but intermingling genres, registers, sociolects, discourses, and ideologies. In *Rabelais and his world* (1965), Bakhtin offered the telling image of the medieval carnival, where unofficial discourses and genres flourished, subversively contesting the centripetal forces of official hegemony.

Balbín, Bohuslav (1621–1688)

M Hirschova, Palacky University, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Bohuslav Balbín was the seventh child born into a gentry family. After the death of his father, the family became impoverished, and young Bohuslav joined SJ at the age of 15. He studied at Jesuit colleges in Bohemia and Silesia, and in 1649 he was ordained as a priest. In the period of a vigorous recatholicization of the heretical Czech lands after the Thirty Years' War, he worked as a missionary and later as a teacher at Jesuit schools. His teaching career ended quickly and under unclear circumstances – Balbín was banned from any contacts with students, and in 1661 he became an SJ historian of the Czech province. His teaching resulted in texbooks of rhetoric (*Quesia oratoria, Brevis tractatio de amplificatione oratoria*) and a general overview of humanities (*Versimilia humaniorum disciplinarum* (1969) – lessons in Latin grammar, style, letter writing, rhetoric, and poetry).

It was his historical research and collection of sources that brought Balbín, a devoted and faithful Catholic, to his patriotism, originating in admiration of the Czech Kingdom history and of the original Czech culture. As a baroque scholar, he paid close attention to the history of locations significant to the Catholic church (especially places and legends connected with the cult of the Virgin Mary). Nevertheless, his *Epitome rerum Bohemicarum* ('A summary of Czech history') could be published only after fulfilling the censorship requirements of the SJ, since it mentioned events and historical personalities unacceptable to the Catholic church.

All Balbín's works were written in Latin. In the 17th and 18th centuries, the status and functional range of the Czech language steadily declined. After the loss of autonomy, when Vienna became the capital, administrative activities were conducted in German (German, Standard), while the major language of religion, education, and culture was Latin. Czech became a vernacular spoken among peasants, used purposefully only in sermons and other religious texts addressed to plain people. Balbín's main work, *Miscellanea historica regni Bohemiae* ('Miscellanea of the history of Czech kingdom') was outlined in 30 volumes, intending to cover not only the history but also the geography and nature of Czech lands. During Balbín's life, only 10 volumes were published. They are still considered a valuable source of historical material.

In the 18th century, the patriotic enthusiasm of Balbín's work appeared to correspond with basic ideas of a newly emerging Enlightenment – efforts to explore history and culture without prejudices. At the same time, all of Balbín's posthumously published treatises were a breeding ground for an early romantic concept of a nation as a community of people, sharing not only a territory and political establishment (a state), but primarily conceiving 'a nation' as shared history, culture, and language. In 1776, Balbin's overview of Czech literature and scholarly writing, *Bohemia docta*, was published, which was important for the early period of the Czech National Revival (a movement aiming for the rebirth of Czech culture and especially language, and later trying to emancipate the Czechs politically).

Even more important was the appearance of Balbín's *Dissertatio apologetica pro lingua slavonica, praecipue Bohemica* ('A defense of Slavonic language, particularly Czech'), finished probably in 1672 and originally not intended for the public. 'A defense of a language' is a historically specific genre merging belles lettres and journalism, with the author's intention to ardently persuade a reader that the language in question (here, Czech), however currently neglected, imperfect, or even condemned, is noble and beautiful. It has to be honored because of its glorious past (wise, noble, and powerful men used to speak, pray, and write in Czech) and it deserves to be supported and

Bohuslav Balbín was the seventh child born into a gentry family. After the death of his father, the family became impoverished, and young Bohuslav joined SJ at the age of 15. He studied at Jesuit colleges in Bohemia and Silesia, and in 1649 he was ordained as a priest. In the period of a vigorous recatholicization of the heretical Czech lands after the Thirty Years' War, he worked as a missionary and later as a teacher at Jesuit schools. His teaching career ended quickly and under unclear circumstances – Balbín was banned from any contacts with students, and in 1661 he became an SJ historian of the Czech province. His teaching resulted in texbooks of rhetoric (*Quesia oratoria, Brevis tractatio de amplificatione oratoria*) and a general overview of humanities (*Versimilia humaniorum disciplinarum* (1969) – lessons in Latin grammar, style, letter writing, rhetoric, and poetry).

It was his historical research and collection of sources that brought Balbín, a devoted and faithful Catholic, to his patriotism, originating in admiration of the Czech Kingdom history and of the original Czech culture. As a baroque scholar, he paid close attention to the history of locations significant to the Catholic church (especially places and legends connected with the cult of the Virgin Mary). Nevertheless, his *Epitome rerum Bohemicarum* ('A summary of Czech history') could be published only after fulfilling the censorship requirements of the SJ, since it mentioned events and historical personalities unacceptable to the Catholic church.

All Balbín's works were written in Latin. In the 17th and 18th centuries, the status and functional range of the Czech language steadily declined. After the loss of autonomy, when Vienna became the capital, administrative activities were conducted in German (German, Standard), while the major language of religion, education, and culture was Latin. Czech became a vernacular spoken among peasants, used purposefully only in sermons and other religious texts addressed to plain people. Balbín's main work, *Miscellanea historica regni Bohemiae* ('Miscellanea of the history of Czech kingdom') was outlined in 30 volumes, intending to cover not only the history but also the geography and nature of Czech lands. During Balbín's life, only 10 volumes were published. They are still considered a valuable source of historical material.

In the 18th century, the patriotic enthusiasm of Balbín's work appeared to correspond with basic ideas of a newly emerging Enlightenment – efforts to explore history and culture without prejudices. At the same time, all of Balbín's posthumously published treatises were a breeding ground for an early romantic concept of a nation as a community of people, sharing not only a territory and political establishment (a state), but primarily conceiving 'a nation' as shared history, culture, and language. In 1776, Balbin's overview of Czech literature and scholarly writing, *Bohemia docta*, was published, which was important for the early period of the Czech National Revival (a movement aiming for the rebirth of Czech culture and especially language, and later trying to emancipate the Czechs politically).

Even more important was the appearance of Balbín's *Dissertatio apologetica pro lingua slavonica, praecipue Bohemica* ('A defense of Slavonic language, particularly Czech'), finished probably in 1672 and originally not intended for the public. 'A defense of a language' is a historically specific genre merging belles lettres and journalism, with the author's intention to ardently persuade a reader that the language in question (here, Czech), however currently neglected, imperfect, or even condemned, is noble and beautiful. It has to be honored because of its glorious past (wise, noble, and powerful men used to speak, pray, and write in Czech) and it deserves to be supported and

cultivated in order to regain its glory. A language is the essence of a national entity, which means that to preserve a language means to preserve (or re-create) a nation at the same time. (It is worth mentioning that in 1775, half of the edition of *Dissertatio* (abbrev.) was confiscated; only in 1869 could the book be published in full.) Later, Balbín's defense became a model of numerous enthusiastic papers with a similar bias. The very phenomenon of defending a language as a main representative of a 'nation' shows a striking feature of Czech culture analyzed and described by Czech semioticist V. Macura: the whole Czech culture at the end of the 18th and in the first three decades of the 19th century was language-based and language-centered, existing primarily through the language; as a matter of fact, it is a metalanguage phenomenon. Czech language functioned as a value by itself, and it was one of the most frequent topics of literary texts. Partially, this was Balbín's legacy.

Balinese

I W Arka, Australian National University, Denpasar Bali, Indonesia

© 2006 Elsevier Ltd. All rights reserved.

Balinese (Bali) is an Austronesian language spoken by some 3 million people, mainly in the islands of Bali and Nusa Penida, Indonesia, but also in western Lombok and in transmigration sites in Lampung (Sumatra) and central Sulawesi. There is a general consensus that Balinese is a member of the Bali-Sasak-Sumbawa subgroup (Esser, 1938; Dyen, 1965; Mbete, 1990), but it is also seen as a member of a wider subgroup that includes Javanese (Blust, 1985).

History and Sociolinguistics

Balinese has had a literacy tradition for over a millennium. The earliest known Old Balinese (OB) texts are inscriptions on copper plaques dated to 882 C.E., concerning royal decrees (Goris, 1954). OB is characterized by the influence of Old Javanese (Kawi) and Sanskrit, which suggests the existence of cultural and language contact between Javanese and Balinese prior to the 9th century. Javanese influence on Balinese intensified in the 14th–15th century, when Bali was controlled by the Javanese Majapahit Kingdom. Old Javanese elements and Sanskrit borrowings began to spread from highly formal – i.e., royal and religious – usage to everyday speech. These helped form the diglossic speech-level system of Modern Balinese, which is absent in OB (see Clynes, 1989, 1995). The speech-level system is invoked by differences in status between speech participants. As shown in **Table 1**, the English 'I' corresponds to several Balinese first person pronouns, each with a different specification of the speakers' and/or addressees' social status, originally based on the traditional caste stratification (Arka, 1998); e.g., *icang* is used when both the speaker and the addressee are low-caste persons. While all of them are still in use now, *tiang* is widely used for polite first person irrespective of the caste of the addressee.

There are quite a large number of words like those in **Table 1** in other categories, such as nouns, verbs,

Table 1

Pronominal forms	*Relevant social information of the participants*	
	Speaker	*Addressee*
nira	god	-
gelah	royal	
titiang	-	highest caste
tiang	-	medium caste
icang	low caste	low caste
kai	-	nonhuman

cultivated in order to regain its glory. A language is the essence of a national entity, which means that to preserve a language means to preserve (or re-create) a nation at the same time. (It is worth mentioning that in 1775, half of the edition of *Dissertatio* (abbrev.) was confiscated; only in 1869 could the book be published in full.) Later, Balbín's defense became a model of numerous enthusiastic papers with a similar bias. The very phenomenon of defending a language as a main representative of a 'nation' shows a striking feature of Czech culture analyzed and described by Czech semioticist V. Macura: the whole Czech culture at the end of the 18th and in the first three decades of the 19th century was language-based and language-centered, existing primarily through the language; as a matter of fact, it is a metalanguage phenomenon. Czech language functioned as a value by itself, and it was one of the most frequent topics of literary texts. Partially, this was Balbín's legacy.

Balinese (Bali) is an Austronesian language spoken by some 3 million people, mainly in the islands of Bali and Nusa Penida, Indonesia, but also in western Lombok and in transmigration sites in Lampung (Sumatra) and central Sulawesi. There is a general consensus that Balinese is a member of the Bali-Sasak-Sumbawa subgroup (Esser, 1938; Dyen, 1965; Mbete, 1990), but it is also seen as a member of a wider subgroup that includes Javanese (Blust, 1985).

History and Sociolinguistics

Balinese has had a literacy tradition for over a millennium. The earliest known Old Balinese (OB) texts are inscriptions on copper plaques dated to 882 C.E., concerning royal decrees (Goris, 1954). OB is characterized by the influence of Old Javanese (Kawi) and Sanskrit, which suggests the existence of cultural and language contact between Javanese and Balinese prior to the 9th century. Javanese influence on Balinese intensified in the 14th–15th century, when Bali was controlled by the Javanese Majapahit Kingdom. Old Javanese elements and Sanskrit borrowings began to spread from highly formal – i.e., royal and religious – usage to everyday speech. These helped form the diglossic speech-level system of Modern Balinese, which is absent in OB (see Clynes, 1989, 1995). The speech-level system is invoked by differences in status between speech participants. As shown in Table 1, the English 'I' corresponds to several Balinese first person pronouns, each with a different specification of the speakers' and/or addressees' social status, originally based on the traditional caste stratification (Arka, 1998); e.g., *icang* is used when both the speaker and the addressee are low-caste persons. While all of them are still in use now, *tiang* is widely used for polite first person irrespective of the caste of the addressee.

There are quite a large number of words like those in Table 1 in other categories, such as nouns, verbs,

Table 1

Pronominal forms	*Relevant social information of the participants*	
	Speaker	*Addressee*
nira	god	-
gelah	royal	
titiang	-	highest caste
tiang	-	medium caste
icang	low caste	low caste
kai	-	nonhuman

adjectives, prepositions and adverbs. They must be individually learned, because the related words are expressed by suppletive forms. The richness of the speech-level system is significant for Balinese verbal arts and linguistic politeness. However, the speech-level system is absent in the Bali Aga or Mountain Balinese (MB) dialect, suggesting that MB is a conservative dialect. Further evidence for this comes from the fact that MB (e.g., in the dialect of Sembiran) retains the Austronesian pronominal *aku* and *engko* and their corresponding bound forms *-ku* and *-mu*. These forms have disappeared in modern Lowland Balinese (LB). LB consists of several dialects showing phonological and lexical variations (Bawa, 1983), with Buleleng and Klungkung varieties being considered representative of standard modern Balinese.

Orthography and Phonology

The traditional Balinese script developed from the Old Javanese script, which itself originated from southern India. It is a syllabic system: a character represents a default CV (Consonant Vowel) syllable with V being phonetically [a] as in Table 2. Any specific opposition is indicated by a diacritical character on top of, below, before, and/or after it, as shown in Table 3. The line, as in the Roman script, runs from left to right.

While modern orthography in Roman script is also now commonly used, especially in paper writing, the traditional script is the only script used in *lontar* (palm leaf) writing. *Lontar* writing and the tradition of *lontar* chanting, called *ma(be)basan*, are still practiced nowadays, primarily for religious purposes. Indonesian, not Balinese, is used as a medium of instruction in schools in Bali. However, Balinese, with its traditional script in paper writing and reading, is taught in primary and secondary schools.

Table 2

ᬲ	(h)a	ᬢ	ta	ᬩ	ba
ᬦ	na	ᬲ	sa	ᬂ	nga
ᬚ	ca	ᬯ	wa	ᬧ	pa
ᬭ	ra	ᬮ	la	ᬜ	ja
ᬓ	ka	ᬫ	ma	ᬬ	ya
ᬤ	da	ᬗ	ga	ᬞ	nya

Table 3

ᬦᬾ	[na]	ᬦᬶ	[ni]	ᬦᬸ	[nu]	ᬦᬾᬭ	[ne]
ᬦᬾᬲ	[nə]	ᬦᬾᬭᬵ	[no]	ᬦᬾᬭ	[nar]	ᬦᬾᬭᬸ	[nur]

Modern Balinese has six vowels, as shown in Table 4. Conventionally, the orthography *e* represents mid front [e] and the central [ə], e.g., *penek* [pənek] 'climb'. Word-final grapheme *a* is pronounced [ə], e.g., *bapa* [bapə] 'father', but as [a] elsewhere, e.g., *bapanne* [bapanne] 'his father'. VV sequences are not diphthongs but are treated as two syllables (Clynes, 1995), possibly with an intervocalic glide in certain dialects, e.g., *liu* [liu]~[liju] 'a lot'.

Eighteen Balinese consonants are shown in Table 5. Word-final /k/ may be also alternatively realized by a glottal [ʔ] in certain dialects, but a glottal stop is not phonemic in Balinese.

Balinese allows a maximally $C_1C_2VC_3$ syllable structure, where only V is obligatory and C2 is restricted to a liquid/glide, e.g., *alih* (V.CVC) 'search', *kranjang* (CCVC.CVC) 'basket', and *meme* 'mother' (CV.CV). Stress is on the final syllable of a root, and a bound morpheme does not generally attract stress, particularly in the Badung dialect, e.g., *jemak* [dʒə.mak] 'take', *jemaka* [dʒə.mak.ə] 'be taken', and *jemakang* [dʒə.mak.əŋ] 'be taken for' (stressed syllables are underlined).

Morphosyntax

Balinese is an agglutinating language with relatively rich verbal and nominal morphology. A typical verbal expression involves a root and a voice morphology, which can be: (i) the homorganic nasal prefix N, indicating an 'active' or 'agentive' voice, (ii) a zero prefix, indicating undergoer or objective voice, (iii) the middle (intransitive) voice prefix *ma-*, which expresses a wide range of meanings, e.g., reciprocal (*madiman* 'kiss each other'), reflexive (*mapayas* 'dress oneself'), agentive (*magae* 'work'), patientive (*makeplug* 'explode'), and stative-passive (*maadep* 'be sold'). A verb may also have a causative or applicative affix. The applicative suffix *-in* is typically associated with a locative or source role, whereas the applicative *-ang* is generally associated with a theme, goal/benefactive, or instrumental role; hence the contrast of *jemak* 'take' → *jemak-in* Y 'take something from Y' vs. *jemak-ang* Y 'take something for Y'. The causative *-in* or *-ang* commonly appears with intransitive bases, but certain transitive verbs may have it, e.g., *diman* 'kiss' → *diman-ang*

Table 4

	Front	*Central*	*Back*

Aff.	V-less			tʃ		
	V-ed			dʒ		
Nasal		m	n	ɲ	ŋ	
Fricative			s			h
Trill			r			
Lateral			l			
Glides		w		j		

'make X kiss Y'. When *-in* and *-ang* appear with the same intransitive base, the derived verb generally contrasts in meaning, e.g., *tegak* 'sit' → *tegak-in* 'sit on something' (applicative *-in*) vs. *tegak-ang* 'make somebody sit' (causative *-ang*), *paek* 'near' → *paek-in* 'move close(r) to something' (applicative *-in*) vs. *paek-ang* 'make something close(r) to something' (causative *-ang*).

Word order is typically S(ubject)–V–O(bject), with S possibly coming after VO. In a double-object construction, the order of the two objects is fixed: S–VO_{Goal}–O_{Theme}.

Balinese appears to have symmetrical objects (Arka, 1998, 2003): either O_{Goal} or O_{Theme} could generally alternate to become S in a nonagentive voice construction, given the right context and intonation contour.

Balinese grammar has been well researched, mainly in the form of Ph.D. dissertations. Hunter (1988) and Beratha (1992) were historical-descriptive in perspective; Artawa (1994) was typological, highlighting the ergativity in Balinese syntax; and Clynes (1995) was also descriptive, focusing on Balinese phonology and morphosyntax (based on the dialect of Singaraja). Pastika (1999) was functional, focusing on the voice selection in Balinese narrative discourse. Arka (1998, 2003) was typological and theoretical, focusing on topics such as phrase structures, argument structures, and (reflexive) binding from a Lexical Functional Grammar (LFG) perspective. Wechsler and Arka (1998) and Wechsler (1999) were theoretical, from a Head-driven Phrase Structure Grammar (HPSG) perspective. Previous work on Balinese, not in the form of dissertations, also consisted essentially of descriptive sketches of grammar, e.g., Kersten (1970), Barber (1977), and Oka Granoka *et al.* (1985).

Dictionaries include Balinese-Indonesian (Warna *et al.*, 1993; Kersten, 1984; Ananda Kusuma, 1986), Indonesian-Balinese (Bahasa, 1975; Ananda Kusuma, 1986; Sutjaja, 2004), Balinese-English (Shadeg, 1977; Barber, 1979; Sutjaja, 2000), English-Balinese (Sutjaja, 2000), Kawi-Balinese-Dutch (Van Der Tuuk, 1897), and monolingual Balinese (Simpen, 1985; Sutjaja, 2003).

Sprachbund

Among the proposed glosses for *sprachbund* are 'linguistic league', 'linguistic area', 'convergence area', and 'diffusion area', but here I will treat *sprachbund* as a loanword into English, like the French *genre*, so henceforth it will be neither capitalized nor italicized. In modern terms, a sprachbund is understood as two or more geographically contiguous and genealogically different languages sharing grammatical and lexical developments that result from language contact rather than a common ancestral source. (Some linguists set the minimum number at three, but I would argue that the convergent and diffusion processes consitutive of a sprachbund are the same for two languages as for three.) In his original formulation of the concept, first in 1923 in a Russian journal article and again in 1928 at the first International Congress of Linguists, N. S. Trubetzkoy used Bulgarian as his example of a language that belongs to the Slavic linguistic family and at the same time to the Balkan sprachbund. In the case of the Balkan sprachbund, the languages are in fact all Indo-European (excluding Balkan Turkic), but they belong to groups that were separated for millennia, and thus, upon coming back into contact, had become sufficiently distinct for contact phenomena to be distinguished from inherited phenomena.

Balkan

The use of the term 'Balkan' (from Turkish, *balkan* 'forested mountain', also the name of a mountain range in Central Bulgaria) to refer to the peninsula also known as Southeastern Europe dates from the 19th century, when European attention turned to Ottoman Turkey, which then included most of what became the Balkan states. As a geographic entity, the Balkan peninsula is unproblematically defined on three sides as the land mass defined by the Adriatic, Mediterranean, and Black Seas, but the northern geographic boundary cannot be set in any nonarbitrary way that is applicable without qualifications in terms of either politics or linguistics. In modern geopolitical terms, from the 1920s to 1991, the Balkans were most frequently understood as comprising Albania, Bulgaria, Greece, Romania, Turkey in Europe, and former Yugoslavia.

The Balkan Languages

For linguistics, the Balkan sprachbund has traditionally consisted of Albanian, Greek, Balkan Romance (BR), and Balkan Slavic (BS). Albanian is divided into two dialects, Gheg north of the river Shkumbi and Tosk south of it. The modern standard is based on northern Tosk. Mainland Greek is also divided between northern and southern dialects at the Gulf of Corinth and the northern frontier of Attica, the southern dialects of the Peloponnese being the basis of the standard vernacular Dhimotiki. During the 19th century, Modern Greek was still called *Romaic*, i.e., 'Roman', a reference to Byzantium as the second

Sprachbund

Among the proposed glosses for *sprachbund* are 'linguistic league', 'linguistic area', 'convergence area', and 'diffusion area', but here I will treat *sprachbund* as a loanword into English, like the French *genre*, so henceforth it will be neither capitalized nor italicized. In modern terms, a sprachbund is understood as two or more geographically contiguous and genealogically different languages sharing grammatical and lexical developments that result from language contact rather than a common ancestral source. (Some linguists set the minimum number at three, but I would argue that the convergent and diffusion processes consitutive of a sprachbund are the same for two languages as for three.) In his original formulation of the concept, first in 1923 in a Russian journal article and again in 1928 at the first International Congress of Linguists, N. S. Trubetzkoy used Bulgarian as his example of a language that belongs to the Slavic linguistic family and at the same time to the Balkan sprachbund. In the case of the Balkan sprachbund, the languages are in fact all Indo-European (excluding Balkan Turkic), but they belong to groups that were separated for millennia, and thus, upon coming back into contact, had become sufficiently distinct for contact phenomena to be distinguished from inherited phenomena.

Balkan

The use of the term 'Balkan' (from Turkish, *balkan* 'forested mountain', also the name of a mountain range in Central Bulgaria) to refer to the peninsula also known as Southeastern Europe dates from the 19th century, when European attention turned to Ottoman Turkey, which then included most of what became the Balkan states. As a geographic entity, the Balkan peninsula is unproblematically defined on three sides as the land mass defined by the Adriatic, Mediterranean, and Black Seas, but the northern geographic boundary cannot be set in any nonarbitrary way that is applicable without qualifications in terms of either politics or linguistics. In modern geopolitical terms, from the 1920s to 1991, the Balkans were most frequently understood as comprising Albania, Bulgaria, Greece, Romania, Turkey in Europe, and former Yugoslavia.

The Balkan Languages

For linguistics, the Balkan sprachbund has traditionally consisted of Albanian, Greek, Balkan Romance (BR), and Balkan Slavic (BS). Albanian is divided into two dialects, Gheg north of the river Shkumbi and Tosk south of it. The modern standard is based on northern Tosk. Mainland Greek is also divided between northern and southern dialects at the Gulf of Corinth and the northern frontier of Attica, the southern dialects of the Peloponnese being the basis of the standard vernacular Dhimotiki. During the 19th century, Modern Greek was still called *Romaic*, i.e., 'Roman', a reference to Byzantium as the second

Rome. BR consists of Romanian, Aromanian, Megleno-Romanian (MR), and Istro-Romanian. Dalmatian, a remnant of West Balkan Romance, whose last speaker died in 1898, is rather poorly attested and generally does not figure in Balkan linguistic accounts. Istro-Romanian is, like Arbëresh (the Albanian of Italy) and Asia Minor Greek (until the exchange of populations between Greece and Turkey in 1923), outside the Balkan geolinguistic area (see 'Balkan Languages vs. Languages of the Balkans'). The Romanian standard is based on the Wallachian dialects of the south, as is the standard of the Republic of Moldova, which at various times has called its official language Moldovan or Romanian. (At present [31 October 2004] the official name is Moldovan.) Aromanian, spoken in Albania, Greece, the Republic of Macedonia, and southwestern Bulgaria (with a large diaspora in Romania, especially Dobrogea) is divided into north/west dialects of Albania and western Macedonia and south/east dialects of Greece and eastern Macedonia. A standard based primarily on the eastern dialect is in use in the Republic of Macedonia. MR survives in seven villages near Gevgelija in the southeast of the Republic of Macedonia and across the border in Greece. During the 19th century, BR was often called Wallachian. The term 'Vlah' can be used as a convenient cover term for BR south of the Danube (Aromanian plus Megleno-Romanian). BS consists of Bulgarian, Macedonian, and the southeast Serbian (Torlak) dialects. Bosnian/Croatian/Serbian (BCS) together with Slovene, form the West South Slavic group, and Macedonian and Bulgarian comprise East South Slavic. The Bulgarian standard is based on its eastern dialects, the Macedonian standard on its west-central dialects. The northern and western boundaries of Torlak as a Balkan dialect are variously defined using phonological or morphological criteria. The narrowest definition is morphological, e.g., the isogloss for the presence of the postposed definite article; the broadest definition is phonological, e.g., the absence of distinctive vocalic length and tone. During the 19th century, BS was often called 'Bulgarian,' and Bulgarian and Serbian linguists and armies fought over where to draw a line between Bulgarian and Serbian. Unable to adjust to modern times, many Bulgarian linguists still cling to the 19th-century practice.

Romani Despite having been summarily dismissed by traditional Balkan linguists, Romani in the Balkans displays many of the same contact-induced structural phenomena and is increasingly present in Balkanological works. Two of the four main dialectal groups of Romani are spoken in the Balkans: Balkan and Vlax (not to be confused with Vlah). The Vlax dialects of Romani take their name from the fact that they took shape in Romania, but they are now dispersed all over Europe and beyond. In the Republic of Macedonia, a Romani standard is emerging on the basis of the Arli dialect of the Balkan group. Unless otherwise specified, references to Romani refer to those dialects spoken in the Balkans.

Turkish Balkan Turkish is divided into two major dialect groups: West Rumelian Turkish (WRT) and East Rumelian. The boundary between the two corresponds roughly to the east-west line of Bulgarian dialects. The Christian Gagauz of Bulgarian and Romanian Dobrudja and Gagauz Yeri in Moldova and adjacent parts of Ukraine speak a language in the Oghuz group – to which Turkish also belongs – which was recognized as official in the USSR in 1957. Although most Balkan linguistic studies treat Turkish as an adstratum, contributing lexicon and phraseology but very little else (aside from evidentiality, see 'Evidential' below), WRT and Gagauz also participate to a certain extent in the Balkan sprachbund. Most of Gagauz, however, ended up in the former Russian Empire, due to migration and border changes. As a result, most of Gagauz is now more influenced by Russian, while the dialectal Gagauz remaining in the Balkans is in need of description.

Jewish Languages Judezmo, the language of the Jews expelled from Spain in 1492, became the majority language among Balkan Jews, overwhelming Judeo-Greek (Yavanic, Yevanic), which survived in the Romaniote liturgy and some enclaves in Epirus. (A written version of Judezmo based on literal translation from Hebrew is known among scholars as Ladino.) Although most speakers of both Judezmo and Judeo-Greek were murdered in the Holocaust, these languages survive as endangered languages and also participated in Balkan linguistic processes.

Balkan Languages vs. Languages of the Balkans There are many other languages spoken in the Balkans in enclaves with varying social relations, e.g., Armenian, Circassian (until 1999), German, Hungarian, Ruthenian, Tatar, Ukrainian, Yiddish, etc. Aside from the dialects spoken in Romania, most of these are outside the geolinguistic Balkans, which for our purposes has a northwest boundary defined by contiguous Albanian dialects that join the major Torlak isoglosses continuing to the Danube. (Such a definition includes the southernmost Slavic dialects of Montenegro as well as the Slavic dialects of northern Kosovo, neither of which fall in the Torlak group. In terms of the Balkan sprachbund, these dialects do show some important transitional features, which will be

noted.) For the most part, the enclave languages were late arrivals or outside the area of intensive diffusion/convergence and did not participate in the type of complex Balkan multilingualism that characterizes the sprachbund as a whole. We can thus distinguish Balkan languages, i.e., those in the sprachbund, from languages of the Balkans, i.e., languages spoken in the Balkan peninsula.

History of Balkan Linguistics

1770–1861

The earliest collections of Balkan linguistic material were intended to eliminate Balkan linguistic diversity. The 1770 Greek-Aromanian-Albanian vocabulary of T. Kavaliotis and the 1793 or 1794(?) Greek-Aromanian-Macedonian-Albanian lexicon of Daniil of Moschopolis (Albanian Voskopoja) were explicitly aimed at the Hellenization of the speakers of other Balkan languages. The first was republished in 1774 by J. Thunmann, who was the first to suggest that Albanians and Romanians were descended from Illyrians, Dacians, and Thracians, thus laying the groundwork for the substratum theory of Balkan linguistics. The second was republished in 1814 by M. Leake, who suggested that similarities among Albanian, BR, and Greek were due to BS influence. His one concrete example was the postposed definite article. It was this same phenomenon that most impressed J. Kopitar, whose 1829 characterization of BR, BS, and Albanian as *drey lexikalisch verschiedenen, aber grammatisch identischen Sprachen* 'three lexically distinct but grammatically identical languages' – which he attributed to the influence of a Thraco-Illyrian substratum – is taken as the earliest formulation characterizing the Balkan sprachbund. Kopitar also noted the replacement of infinitival with subjunctive constructions and the formation of the future using 'want' as shared with Greek and Serbian as well.

A. Schleicher is sometimes cited as the first to formulate the Balkan sprachbund in 1850, when he writes of Albanian, BR, and BS saying *eine Gruppe aneinandergränzender Sprachen zusammengefunden hat, die bei stammhafter Verschiedenheit nur darin übereinstimmen, dass sie die verdorbensten ihrer Familie sind* ('a group of propinquitous languages has coalesced that, being of different lines of descent, agree only in the fact that they are the most corrupt in their families'). However, since he gives no indication of the causes of this 'corruption', his formulation differs from Kopitar's mainly in its ideology of language change as degeneration.

The next real advance in the development of Balkan linguistics was F. Miklosich's 1861 article on Slavic elements in Romanian, which added genitive-dative merger (see 'Genitive-Dative Merger'), object pronoun doubling (see 'Resumptive Clitic Pronouns [Reduplication, Replication]'), and the formation of teens (see 'Numeral Formation: The Teens'). Miklosich accorded more attention to Greek and was also the first to adduce a number of phonological changes, including the development of stressed schwa (see 'Vowel Reduction and Raising') and the raising of unstressed /a/ and /o/ to schwa and /u/, respectively (see 'Stressed Schwa').

1861 Onward

The next six decades were characterized by the gathering of materials relating to specific Balkan languages or specific aspects of individual or pairs of Balkan languages. The 1920s saw the basic syntheses and theoretical formulations that continue to inform the field. Trubetzkoy's contribution has already been described. In 1925, A. Seliščev attempted a balanced account of Turkish, Slavic, Latin, Greek, and substratum languages as the sources of various Balkanisms, i.e., the similarities among the Balkan languages that can be attributed, at least in part, to shared, contact-induced change. Sandfeld (1930) tried to attribute almost all the commonalities of the Balkan sprachbund to the influence and prestige of Byzantine Greek. Other scholars have laid particular emphasis on Balkan Latin as the primary causal factor, while our knowledge of the pre-Latin non-Hellenic languages of the Balkans remains too meager for almost any serious speculations beyond the lexicon.

While the 1920s saw the establishment of Balkan linguistics as a subdiscipline within linguistics, the period from 1930 to 1960 was characterized by slow growth and was also the period when the insights gained in Europe finally came to the attention of North American linguists. From the 1960s onward, there has been a constant increase in the production of studies pertaining to the Balkan languages and Balkan linguistics. At the same time, studies of such contact-induced phenomena as creolization, code switching, and language shift have led to the identification of contact linguistics as an overarching field of study. More recently, in the past decade or so, a renewed interest in linguistic typology has brought forward questions of the extent to which the Balkan sprachbund is or is not part of a larger European linguistic area, defined more by typological profile without necessarily identifying specific paths of diffusion or convergence. We will return to the question of Eurology vs. Balkanology in 'Causation'.

Balkanisms

This section surveys some of the principal Balkanisms (see '1770–1861') as identified during the course of the past two centuries. Although system, not mere inventory, must be the basis of detailed study, and a given surface phenomenon may function differently in different systems, it is nonetheless convenient to use lists as a kind of shorthand for the systemic relations that can yield the most insights. We do not want to fetishize the labels for these systemic manifestations, assigning numeric values to them and tallying up the number of points a language 'scores'. Rather these labels stand for complex interrelations that include differences as well as similarities that must be elucidated in their larger contexts (cf. Friedman in Reiter, 1983).

Phonology

In contradistinction to linguistic areas such as the Caucasus, the Northwest Coast, and South Asia, where phonological features such as glottalization and retroflexion are among the most salient commonalities, there are no truly pan-Balkan phonological features. Rather, there are articulatory tendencies of greater or lesser extent.

Vowel Reduction and Raising The reduction of unstressed vowels to schwa or nonsyllabic elements (and thence sometimes to zero) as well as the raising of unstressed mid-vowels (/e/ and /o/) to high vowels (/i/ and /u/, respectively) can be treated as Balkan, albeit not pan-Balkan. Both Albanian and BR show a tendency to reduce unstressed vowels as early as the Latin period, e.g., Lat. *imperātor* > Albanian *mbret* and Romanian *împărat* 'king'. While shared phonological tendencies in Albanian and BR, like shared vocabulary of pre-Latin origin, are attributed by some scholars to substrate influence, the evidence of vowel reduction in Western Romance leads other scholars to suggest that this is a typological rather than an areal feature. Nonetheless, the raising and/or elimination of unstressed vowels is characteristic of southeastern Macedonian, eastern Bulgarian, northern Greek, BR, and Gheg, although the details differ among these languages.

Stressed Schwa All the Balkan languages and their dialects possess the classic European five vowel system /a, e, i, o, u/, at least under stress. A phenomenon common in the Balkans is the existence of a stressed schwa, but its status as a contact-induced phenomenon is not pan-Balkan. Greek lacks stressed schwa altogether. In Macedonian, almost all the dialects outside the west-central area have stressed schwa, but of different origins in different areas, and some western peripheral dialects also lack stressed schwa. Most of Bulgarian has stressed schwa, but not the Teteven-Erkech and central Rhodopian dialects. In Albanian, stressed schwa develops from nasal *â* only in Tosk, but it is incorrect to characterize all of Gheg as lacking stressed schwa, since it also occurs in central Gheg as a result of later processes. Romani has schwa when in contact with languages that have it. WRT has a tendency to lower and front the high back unrounded vowel to schwa.

Other Vowels Most Balkan languages lack front rounded vowels, but most of Albanian has /ü/, or, in West Central Gheg, /ö/. Southern Montenegrin dialects in contact with Albanian also have /ü/, but East Central Gheg, which is mostly in Macedonia, unrounds /ü/ to /i/, as does southernmost Tosk (Lab, Çam, Arvanitika), in contact with Aromanian and Greek (which also merged /ü/ with /i/, a change that had not yet been completed in the 10th century). Similarly, WRT tends to eliminate /ö/ by merging it with /o/ or /ü/ (more rarely /e/), and /ü/ (like /u/ and /ɯ/) becomes /i/ word finally. Other vocalic phenomena that have been suggested are relatively localized.

Consonants The alternation of clear /l/ before front vowels and velar /ł/ elsewhere is characteristic of BS (including Torlak but not the rest of BCS), Northern Greek, Balkan Romani, and Vlah, but not Albanian, where the two sounds are in phonemic contrast, nor Daco-Romanian and Southern Greek, where only clear /l/ occurs. Aromanian has Greek and Albanian interdental and Greek voiced velar and palatal fricatives in loanwords from Albanian and Greek, but these tend to be replaced by corresponding stops and the palatal glide by speakers who do not know Greek or Albanian, particularly the younger generation in Macedonia.

Aside from Greek, most Balkan languages have an opposition between strident palatal affricates, on the one hand, and mellow palatals, dorso-palatals, or palatalized velars, on the other. The opposition is neutralized in Albanian, BS, and WRT dialects in Kosovo, parts of Western Macedonia, and along the Serbo-Bulgarian border. Northern Greek has palatals lacking in the south.

In western Macedonia, the velar fricative is generally lost or replaced in Albanian, Macedonian, and WRT, a phenomenon that extends into parts of Kosovo, as well as adjacent Serbia, much of Montenegro, and Bosnia-Herzegovina, where the preservation of BCS /x/ is characteristic of Muslim and some Catholic dialects now Bosnian and Croatian, respectively.

In the northern Gheg of Malësia e Madhe, final devoicing is a phenomenon shared with adjacent Montenegrin dialects. It is worth noting that final devoicing is atypical for most of the rest of BCS and Gheg, and it appears rather to be a Macedonian feature extending into this region. Such influence also seems to be the case in the transitional Gheg and northern Tosk dialects. Some of the Romani dialects in this region also have final devoicing, and in the WRT of these regions final devoicing, which is usually limited to stops in Turkish, extends to fricatives. Five of the seven MR villages also have final devoicing.

Prosody Although prosodic distinctions of length, and in some cases pitch, were present in the attested ancestors of the Balkan languages, the modern Balkan languages are generally characterized by the absence of length and tone and the presence of a stress accent that usually does not move further back in the word than the antepenultimate syllable. If stress does move further back, there is usually a secondary stress on one of the last three syllables. However, Northern Gheg and Southern Tosk preserve Common Albanian length, and Southeastern Macedonian has new long vowels as the result of loss of intervocalic consonants and elision. Similar new long vowels occur in Gora, a string of Slavic-speaking Muslim villages along the western and northern slopes of Mounts Korab and Šar in northeastern Albania and the southwestern corner of Kosovo. The most significant isoglosses (fixed antepenultimate stress, postposed article, etc.) link Goran with the northwest Macedonian dialects rather than with the Serbian of Prizren.

Morphosyntax

Grammaticalized Definiteness In BS, BR, and Albanian, native demonstrative pronouns have been encliticized or suffixed to nominals (normally the first in the noun phrase) and become definite articles. The article follows a plural marker, if any, and in BS the clitic-like nature of the article is seen in that it does not trigger certain morphophonemic alternations, e.g., Macedonian *starec* 'old man', *starci* 'old men' but *starecot* 'the old man' and not **starcot*. Hamp (1982) adduces evidence suggesting that the autochthonous language that became Latinized into Romanian and with which the ancestor of Albanian was in contact might already have had a postposed definite article by the time of contact with Latin. Common Slavic already had a postposed relative pronoun **jĭ* affixed to adjectivals to denote definiteness, as this phenomenon is attested in Old Church Slavonic (OCS; 9th–11th centuries), and the morphology (but not the grammatical meaning) survives in Slavic outside the geopolitical Balkans. Remnants of this older definite/indefinite opposition survive in West South Slavic adjectives, and traces of the morphology occur in BS, e.g., Macedonian *star* 'old INDEF. MASC', *stariot* 'old DEF.MASC', where the /i/ indicates that the newer definite article has been suffixed to a definite adjectival form. Scandinavian and dialectal North Russian also have postposed definite articles of pronominal origin, and Czech, which has been in close contact with German, has uses of its deictics that are basically articular. These typological parallels and historical antecedents, however, do not change the fact that the BS postposed definite article developed during the period of its contact with BR and Albanian.

Greek and Romani have preposed definite articles, both based on native material. In the case of Greek, the pronoun that became an article was still mostly demonstrative and was facultative except with proper names in Homeric, but it was obligatory in Attic. Romani articles look like borrowings from Greek, e.g., MASC NOM SG *o* FEM NOM SG *i*, but the oblique forms /le/ and /la/ in Vlax dialects demonstrate that the Romani articles are derived from native demonstratives, reflecting the regular change of $*t > l$, which occurred prior to contact with Greek. It was contact with Greek, however, that triggered the transformation of native material into definite articles, and Romani usage patterns very much like Greek. Romani dialects outside the Balkans in contact with languages lacking definite articles tend to lose them.

The use of an atonic form of the numeral 'one' as an indefinite article is characteristic of the Balkan languages and, even though such developments are common in many languages, is arguably a Balkanism. 'One' was not used in this function in OCS, Ancient Greek, or Latin, but it was so used in Orkhon Turkic (8th century C.E.). To this we can add the fact that such usage does not occur in East Slavic. Usage in Turkish, Albanian, and BR is at a similar level of frequency to that of English, although details in individual grammars will cause some lack of isomorphism. Usage in BS and in Greek is approximately half that of the other Balkan languages, while usage in Romani in the Balkans patterns with BS and Greek, and Romani elsewhere patterns like its contact languages. An indication that this is an areal phenomenon despite the occurrence of such usages in Western Europe and elsewhere is the fact that, as one moves north and east through West South Slavic territory, the usage becomes increasingly restricted.

Finally, we can mention here the phenomenon of double determination, i.e., the presence of a definite article on a noun modified by a demonstrative pronoun. Such usage occurs in Greek, BR, BS, Albanian,

and Romani, although the rules and relative frequency and acceptability of the construction vary. In Greek it is obligatory, e.g., *autós o ánthrōpos* or *o ánthrōpos autós* but not **autós ánthrōpos* 'this person'. In Romanian, the article is not used if the deictic is preposed, but is used if it is postposed (and the deictic takes the so-called deictic particle *-a*): *omul acesta* but *acest om* 'this person', cf. Aromanian *aistã carte*, *cartea aistã* 'this book'. Megleno-Romanian has frequent double determination *tsista lup-u* 'this wolf-DEF', but indefinite nouns also occur *tsista drāc* 'this devil-INDEF'. In Albanian, the deictic is preposed to either the indefinite or definite: *ai njeri*, *ai njeriu* 'this person'. In BS, double determination occurs but is considered dialectal, Macedonian *ovoj čovekov* (vs. *ovoj čovek*) 'this person', or Torlak *taja starata* 'that old [lady]'. Romani permits but does not require the use of a definite article with a demonstrative, in which case the article must precede the substantive but the demonstrative can precede or follow: *kova manuš*, *kova o manuš*, *o manuš kova* 'this person'. Double determination or the order noun-determiner is pragmatically more thematic in the discourse.

Resumptive Clitic Pronouns (Reduplication, Replication) Balkan languages are characterized by the use of clitic or weak resumptive object pronouns that agree in gender, number, and case with the nonclitic/strong pronoun or substantive they refer to. This phenomenon is called (object/pronoun) reduplication/doubling in Balkan linguistics and is connected to expressions of definiteness, referentiality, and animacy: the first candidates for reduplication are personal pronouns (inherently definite and, in the first two persons, usually human), then indirect objects (usually human, often topicalized), then definite direct objects, and finally specific or topicalized direct objects.

From a morphosyntactic point of view, there are four types of reduplication: pronominal object doubling, substantival object replication, pronominal possessive doubling, and substantival possessive replication. All four phenomena can be illustrated in the following Macedonian sentence:

Tatko mi	moj	i	majka
father me.DAT	*my.M*	*and*	*mother*
mu	na car-ot	im	rekoa
him.DAT	*to king-the*	*them.DAT*	*said.3PL.AOR*
nim	da	mu	gi
them.DAT	*SP*	*him.DAT*	*them.ACC*
dadat	knigi-te	na	dete-to
give.3PL.PRES	*books-the*	*to*	*child-the*

'My father and the king's mother told them to give the books to the child.'

The first three of these expressions are facultative and could be replaced by *tatko mi*, *majkata na carot* (*majka* is definite), and *im*, respectively. The reduplication serves to emphasize or focus the referent of the reduplicated pronoun. The last set of reduplications, *mu . . . na deteto* and *gi . . . knigite*, are obligatory in standard Macedonian and, for the most part, in the western dialects on which it is based. The norm requires reduplication for definite direct objects and all indirect objects. In practice, however, even the most normative grammar shows that specificity or topicalization rather than definiteness is the trigger (Koneski, 1967: 232):

kako	vistinski	ja	doživuvame	edna	situacija
how	*truly*	*it.ACC*	*experience. 1PL.PRES*	*one*	*situation*

'how we actually experience a [given] situation'

Pronominal object doubling occurs in all of BS (and southern Montenegro), BR, Albanian, Greek, and Romani. It is conditioned by discourse factors such as emphasis or focus and can be compared to the use of subject pronouns. Just as the fact that the subject is marked on the verb makes the subject pronoun redundant unless there is a need for emphasis or specification, so, too, the clitic pronominal object, which is the required form if the object is a pronoun, makes the full form redundant except under similar discourse-bound circumstances. The absence of such doubling from the rest of BCS is a diagnostic separating Balkan from non-Balkan Slavic.

The clitic replication of oblique nominals shows how grammatical change can enter a language via discourse phenomena and at the same time supports Topolińska's observation that analytic markers of referentiality are characteristic of convergent development. Object reduplication is another scalar Balkanism. It is rare in Torlak and used only for emphasis and thus separates East from West South Slavic. Similar conditions hold for Romani except in possessive constructions. Object reduplication is more pragmatically conditioned and less grammaticalized in Bulgarian, Romanian, and Greek, where the phenomenon signals topicalization, focus, or emphasis, and is restricted by factors such as animacy (or humanness) and degree of referentiality (definiteness, specificity, determinacy, etc.). In Albanian, Vlah, and West Macedonian, reduplication has become grammaticalized. It is most frequent in Macedonian, where, unlike in the other Balkan languages, it can even occur (facultatively) with indefinite indeterminate pronouns such as *nikoj* 'nobody'.

While it lacks a definite article, Turkish does have a special accusative marker used for definite or specified direct objects. The following proverb illustrates

how the Turkish definite accusative is rendered by Balkan object reduplication. Note that Greek and Bulgarian have reduplication with an indefinite object, indicating its specificity:

Turkish:	Yavaş	başı	kılıç	kes-mez (Turkish)		
	gentle	*head-DEF.ACC*	*sword*	*cuts-not*		
Bulgarian:	Pokorena	glava	sabja	ne	ja	seče
	bent	*head*	*sword*	*not*	*it.ACC*	*cuts*
Greek:	Kefáli	proskynēméno	spathì	dhèn		
	head	*bent*	*sword*	*not*		
	tò	kóvei				
	it.ACC	*cuts*				
Romanian:	Cap-ul	plecat	nu	l	taie	sabia
	head-DEF	*bent*	*not*	*it.ACC*	*cuts*	*sword.DEF*
Albanian:	Kokën	e	falur	yatagan-i		
	head	*PART.F.DEF.ACC*	*bent*	*sword-DEF*		
	nuk	e	pret			
	not	*it.ACC*	*cuts*			

'A/The sword does not cut off a/the bent head'
(= Keep your head down.)

Possessive doubling is a more restricted phenomenon. The use of dative clitics to indicate possession in Macedonian is limited to kinship terms, Aromanian has special possessive clitics that can only be used with kinship terms, and Albanian also has special possessive constructions for kinship terms. In Bulgarian, possession is usually signaled by a dative clitic following the definite form of the noun, and possessive adjectives, which are the norm in Macedonian, are more emphatic in Bulgarian. In Greek, clitic dative pronouns after the definite form of the noun is the normal manner of indicating possession, and emphasis is rendered by adding the appropriate form of the adjective *dikós* '[one's] own' immediately before the pronoun. However, pronominal doubling is also used colloquially for emphasis:

to	vivlio	mou	mena
the	*book*	*me.GEN*	*me.GEN*

'**my** book'

Romanian also has such clitic doubling colloquially:

propria-mi	mea	semnătura
own.FEM-me.DAT	*my*	*signature.DEF*

'my very own signature'

Substantival possessive replication occurs in all the Balkan languages, but the details differ from language to language. The Turkish construction of genitive possessed plus pronominal suffix on the possessor is the normal pattern:

kral-ın	anne-si
king-GEN	*mother-his*

'the king's mother = the mother of the king'

Genitive-Dative Merger Albanian, BS, BR, and Greek have no formal (i.e., surface) distinction between the shape of the genitive and the shape of the dative, the dative having replaced the genitive except in Greek, where the genitive replaced the dative. The same forms thus do double duty for marking possession and indirect objects. Romani and WRT maintain the genitive/dative distinction, and the situation is more complicated in Albanian and MR. Albanian has merged genitive and dative but has a distinct ablative. The dative is used as the object of a verb, the genitive is preceded by a particle of concord, and the ablative is the object of certain prepositions or in apposition to another substantive. In the indefinite plural, however, Albanian has a special ablative form in *-sh*. Pronominal declension also has a distinct ablative form used with certain prepositions, NOM *nga unë/djali* 'from me/the boy', ACC *për mua/djalin* 'for me/the boy', DAT *më tha mua/i tha djalit* 'he told me/the boy (with initial clitic reduplication)', ABL *prej meje/djalit* 'from me/the boy'. MR preserved a remnant of the genitive-dative distinction, albeit only in the speech of the oldest generation: *cari* 'who' *pe cari* 'whom.ACC', *la cari* 'to whom.DAT' but *al cruj* 'of whom, whose'. Elsewhere, the dative and accusative are distinct, and the genitive is identical to the dative.

Analytic Case Relations All the Balkan languages have simplified their inherited patterns of inflection. Eastern Macedonian and colloquial Bulgarian have gone the farthest, completely eliminating all traces of case morphology other than accusative personal pronouns and accusative vs. dative clitics. The marking of nonclitic dative objects is by means of the preposition *na* and the accusative pronoun. All other case relations are likewise indicated syntactically throughout BS, usually by a preposition but sometimes just by apposition. Western Macedonian preserves a distinctive set of dative synthetic pronouns, and, in the dialects that serve as the basis for the standard, a few remnants of animate singular masculine accusatives. As one moves further to the periphery of BS in the southwest and north, the complexity of case marking increases to include feminine accusatives, masculine datives, feminine datives, and eventually, in Gora and Torlakia, oblique plurals. In the Torlak dialects and the Macedonian dialects around Korça in Albania, case marking also occurs in the definite article. The other Balkan languages all retain at least three distinct cases (nominative, accusative, and genitive-dative).

Balkan Romani and WRT both preserve their full inflectional systems, but with tendencies toward simplification that show an intersection between the areal and typological. From a typological point of view, it is the peripheral cases that are expected to be lost first, and this is precisely what happens. Thus, WRT exhibits dative-locative confusion:

gittı-k	Selanik-te
went-1PL.AOR	*Salonica-LOC*

'We went to Salonica'

There is also a tendency to eliminate case marking in locational postpositions:

ürti	üsti [vs üstü-n-de]	kedi-ler
blanket top	*top-its-LOC*	*cat-PL*

'on top of his blanket [there were] cats'

Romani dialects in contact with BS tend to replace the locative with the dative and the dative, locative, and ablative with prepositional constructions derived from case affixes, themselves of postpositional origin:

jekh-e	aindž-a-te	vs.	jekh-e	aindž-a-ke	>	k-i jekh aindž	
one-OBL	*field-OBL-LOC*		*one-OBL*	*field-OBL-DAT*		*to-FEM one field*	
'in a field',			'to a field'			'in/to a field'	

aindž-a-tar	=	tar-i aindž
field-OBL-ABL		*from-FEM field*

'from a field'.

Outside the pronouns, a distinct Romani accusative is limited to animate (or in some dialects referential) nouns, while in Turkish accusative marking is limited to definite or specific direct objects (see 'Resumptive Clitic Pronouns' [Reduplication, Replication]).

The vocative survives in all the Indo-European Balkan languages, and some argue that this preservation is a shared archaism, reinforced by contact, which is consistent with the direct encounters that lead to contact phenomena. It runs counter to the tendency toward analytism, however.

Analytic Gradation of Adjectives Although the comparative is analytic in all the Balkan languages, remnants of synthetic comparatives survive at the peripheries, i.e., Greek has a number of inflected comparative forms, and northern Torlak preserves a very limited set. In the rest of BS, analytic comparatives with *po* are realized with almost complete consistency. Southern Montenegrin dialects also have analytic adjectival gradation using the same markers. BR, Albanian, and most Balkan dialects of Romani have complete consistency in the analytic marking of the comparative, the markers being *mai* (<*magis*) in Romanian and Megleno-Romanian, *cama* (*quam* + *magis*) in Aromanian, *më* in Albanian, and borrowed in Romani (generally the marker of the main contact language, but Slavic *po* and Turkish *da[h]a* are both more widespread). Remnants of a synthetic comparative in *-eder* also survive in some Romani dialects, but generally those spoken outside the Balkans. Given that Romani entered the Balkans some time between the 10th and 13th centuries, and given that during this same period Slavic preserved its inflectional system of adjectival gradation, it would appear that BS and Romani were undergoing this shift at about the same time, and those dialects that left the Balkans did so before its completion.

In general, the standard of comparison is an ablative marker, which is synthetic in Turkish and most of Romani but prepositional (lexical 'from') in BS, BR, Greek, some Romani, and Albanian, particularly Tosk. Albanian can also use relative *se* and BR can have relative *ca*. Clausal comparisons (e.g., 'to eat is better than to sleep') in Albanian, BR, and BS involve quantifiers, *se [sa]* 'that [how much]', *de.cît* 'from. how much', *ot.kolko[to]* 'from.how much [that]', respectively. Greek has *pará* 'contrary to, despite'.

There is a bifurcation in the superlative between Turkish and BS, on the one hand, and Greek and Albanian on the other, with BR and Romani occupying a middle ground. In Turkish and BS, the relative superlative is purely analytic and uses native markers: Turkish *en*, BS *naj*. In Greek and Albanian, the relative superlative is expressed by the definite of the comparative. (Greek also has a synthetic absolute comparative in a few adjectives.) Romanian and most of MR pattern like Albanian, whereas Aromanian and the MR of Tsãrnareka have borrowed Slavic *naj*.

The expression of analytic adjectival gradation in Turkish is attested in the oldest monuments (8th century). The Greek dialects of Epirus, Thrace, Asia Minor, and of the Sarakatsan (transhumant Hellenophone shepherds) use the comparative marker *[a]kóm[a]* 'yet, still', calquing exactly Turkish *daha* (Table 1).

In Moldavian Gagauz, *sam* (<Russian *samyj*) is in competition with *en* as the superlative marker for the younger generation of speakers.

Numeral Formation: The Teens The formation of teens by means of a construction meaning 'numeral on ten' is pan-Slavic but absent from Baltic, occurs in BR but not the rest of Romance, and is also Albanian. Although assumed to be a calque from BS into BR and Albanian, Hamp (1992) has pointed out that the words for 'twenty' in BS and BR and 'thirty' in Albanian show the numeral 'ten' is masculine in Slavic but feminine in Albanian and BR. Based on the isomorphism in gender for BR and Albanian and a combination of old shared sound changes and ancient

Table 1 Balkan adjectival gradation

Turkish	daha	büyük	ablative	en büyük
Romani (Arli)	po/da[h]a	baro	ablative	en/naj baro
Bulgarian	po-	goljam	ot	naj-goljam
Macedonian	po	golem	od	najgolem
Aromanian	kama	mari	di	nai mari
MR (Tsărnareka)	mai	mari	di	naimar[l]i
				most big
MR	mai	mari	di	tsăl mai mar[l]i
Romanian	mai	mare	de[cît]	cel mai mare
Albanian (Tosk)	më	i madh	nga	më i madhi
Greek	pio	megálos	apó	o pio megálos
	more	big	from	the more big
	'bigger than'			'biggest'

Table 2 Balkan teens and tens[a–f]

OCS	edinŭ	na	desęte
Romanian	un	spre	zeci
Aromanian	ună	spră	[dzătse]
MR	un	spră	ts
Albanian (Tosk)	një	mbë	dhjetë
	one	*on*	*ten*
Greek	enteka (en[a] deka)		
	one ten		
Romani	deš u jekh		
	ten and one		
Turkish	on bir		
	ten one		
	'eleven'		

[a]Slavic gender in numerals: dva (MASC) dve (FEM) 'two'.
[b]Romanian gender in numerals: doi (MASC) două (FEM) 'two'.
[c]Albanian gender in numerals: tre (MASC) tri (FEM) 'three' (dy [MASC], dȳ [FEM] 'two').
[d]OCS 10 = MASC dŭva desęte 'twenty'.
[e]Romanian 10 = FEM două zeci 'twenty' (zece 'ten' < Lat. decem).
[f]Albanian 10 = FEM tri dhjetë 'thirty'.

borrowed lexicon among the three, Hamp suggests that this innovation occurred at a time when the Indo-European dialects that became Slavic, Albanian, and the language that Latinized into Romanian were part of a Northwest European sprachbund prior to their respective migrations to the Balkans (Table 2).

Analytic Subjunctive The analytic subjunctive formed by means of a subordinating particle (SP), usually of pronominal origin, plus a finite verb agreeing with its subject (omitted if the same as in the main clause, specified if different) replaces older nonfinite complements (infinitives) in all Balkan languages to varying degrees. Gheg has a new infinitive employing the preposition *me* 'with' and a short participle in contexts where Tosk uses the analytic subjunctive, but Gheg also has uses of the analytic subjunctive, and Tosk has some nonfinite participial constructions where other Balkan languages have the analytic subjunctive. Romanian and MR still have remnants of the Latin infinitive that can be used in some traditional infinitival functions. The BR infinitive is strongest in Maramureş, the northernmost Romanian region and the one in most contact with infinitive-using languages (Ukrainian, Hungarian, formerly Yiddish). BR in general also preserves Latin infinitives in *-re* as verbal nouns. Greek has a morphological remnant of the infinitive, but its only living function is to represent the main verb in perfects and pluperfects. Bulgarian has a very marginal remnant of the Slavic infinitive limited to subordination to a tiny number of verbs. The infinitive has disappeared completely from Torlak except in some folk songs. Macedonian and Romani have eliminated all traces of earlier infinitives. Thus the replacement of infinitives with subjunctives is not uniform but scalar. At one end is Gheg, followed closely by Romanian, then Tosk, Bulgarian, Greek, and Vlah, with Torlak, Romani, and Macedonian at the other end.

New infinitival constructions have arisen in Romani outside of the Balkans in contact with infinitive-using languages. In Macedonian, some uses of the verbal noun can replace SP-clauses and thus function as a kind of new infinitive, although these constructions, which are highly colloquial, are merely alternatives. The option of using an SP-clause rather than an infinitive is available to all of BCS, but there is a tendency for such usage to become more frequent as one moves from northwest to southeast in the direction of Torlak. Since 1991, Croatian language planners have identified SP-clauses with Serbian and infinitives with Croatian, as a result of which Croatian speakers are now discouraged from using SP-clauses. In Serbian and Bosnian, however, the two constructions continue to coexist amicably (Table 3).

In WRT, optatives have expanded at the expense of infinitives owing to the influence of the other

Table 3 Balkan SP clauses

Romani	mangav	te	hramonav
Albanian (Tosk)	dua	të	shkruaj
Albanian (Gheg)	[due	me	shkrue]
Greek	thélō	na	gráfō
Bulgarian	iskam	da	piša
Macedonian	sakam	da	pišuvam
Torlak	oču	da	pišem
Romanian	vreau	să	scriu
Vlah	voi	s(i)	scriu
gloss	*I.want*	*SP*	*I.write*
WRT	isterim		yazayım
gloss	*I.want*		*I.write.OPT*
	'I want to write'		

Table 4 Balkan futures

Romani	ka		dža[s]
Albanian (Tosk)	do	[të]	shkojmë
Greek	tha		páme
Bulgarian	šte		trŭgnem
Macedonian	ḱe		odime
Torlak	če		odime
Romanian (Colloquial, South)	o	să	mergem
Aromanian	va	s-	neadzim
MR		si, să	neadzim
[MR-Tsãrnareka	ãs		neadzim]
English	*we will go*		

Balkan languages. The usage in Table 3 was a possibility in older Turkish, but, in a classic case of convergence via feature selection, the WRT optative now occurs where Turkish would normally have a nonfinite construction:

ben seni ist-er-im şimdi bir
I you.ACC want-PRES-1SG now one
müneccim ol-a-sın
astrologer be-OPT-2SG
Now I want you to be an astrologer

Similarly, Balkan Judezmo, which preserves the Spanish infinitive, nonetheless has some uses of its subjunctive, e.g., in questions, that calque Balkan SP-clauses and do not occur in Modern Spanish or North African Judezmo:

kwando ke te vengamoz a tom-ar? (Balkan Judezmo)
when that you.ACC we.come to take-INF
Póte na 'rthoúme na se pároume? (Greek)
when SP we.come SP you.ACC we.take
Koga da ti dojdeme da te zemame? (Macedonian)
when SP you.DAT we.come SP you.ACC we.take
Cuándo quieres que vengamos a recog-er-te? (Modern Spanish)
when you.want that we.come to take-INF-you
'When do you want us to come to get you?'

All Balkan languages use the independent analytic subjunctive to express wish, desire, or a milder form of imperative. Albanian also has a synthetic optative used mostly in formulae.

Futures in 'Will' and 'Have' When Slavic entered the Balkans (6th–7th centuries C.E.), there was competition between the auxiliaries 'have' and 'want (will)' + infinitive to mark futurity in Latin and Greek, with Latin favoring 'have' and Greek favoring 'want'. OCS used the perfective of 'be' in addition to 'want', 'have' and various forms of 'begin' + infinitive. The 'will' + infinitive construction survives (with modified or new infinitives) in Romanian, northwestern Gheg (near and in Montenegro), in Bulgarian dialects (with postposed auxiliary), and MR (for speculations and threats). This form also survives in all the non-Balkan Štokavian dialects of BCS and connects them with East South Slavic. In fact, much of Štokavian ended up in its current location as a result of northward migrations during the 15th–18th centuries. The rest of Slavic developed the perfective of 'be' as a future marker. The next stage was 'will' + SP + conjugated present tense verb (Greek 14th century, Slavic 15th century). This stage also survives in BCS, including Torlak. The third stage, which overlaps the second, is the transformation of 'will' into an invariant particle + SP + conjugated main verb. This type of construction is still the main one in Tosk and parts of Gheg, especially in the northwest and southeast peripheries; it is characteristic of southern Romanian and survives in Torlak and in certain modal uses in East South Slavic, but not in Greek. The fourth stage is the elimination of the SP so that the future is marked by an invariant particle plus a conjugated verb. In addition to being the standard future in Balkan and southern Vlax Romani, Greek, and BS, it is common in colloquial Tosk. In MR, the future marker merged with SP, producing a new particle, *ãs*, in Tsãrnareka, but eliminating a distinct future marker in the other villages. Romani outside the Balkans has other means of forming or expressing the future, and it appears that the Romani development in the Balkans occurred in concert with the other Balkan languages (cf. 'Analytic Gradation of Adjectives') (Table 4).

Conjugated 'have' + infinitive, attested for early stages of all the traditional Balkan languages, remains the predominant future in most of Gheg. Conjugated have + SP + present is still used in Romanian, and invariant 'have' (which can also be an existential in all the Balkan languages with lexical 'have', cf. French *il y a*) is used in Arbëresh and occurs with modal

Table 5 Negated futures

Macedonian	nema		da	odime
Bulgarian	njama		da	hodime
Aromanian	noare		s'	neadzim
	not.has		SP	we.go
Romani	na-e	amen	te	dža[s]
	not-is	*we.ACC*	*SP*	*go.IPL.PRES*
WRT	yok-tur			gid-elim
	not-is			*go-OPT.1PL*
English	*we won't go*			

functions in BS. In East South Slavic, the ordinary negated future uses this negative existential + SP + present, and this type is calqued into Aromanian, Romani, and WRT. Since Turkish and most of Romani lack lexical verbs meaning 'have', their calques use their negated existentials, which also code possession (Table 5).

Future in Past as Conditional The combination of a future marker with a past tense marker to form a conditional, especially irrealis, is a classic Balkanism, although its realization differs among the various Balkan languages. (The construction itself can have a variety of related meanings, e.g., 'X almost happened/was about to happen', iterative-habitual, anterior future, and languages and dialects can be differentiated on the basis of which of these meanings are encoded.) Greek, Macedonian, and Romani all use the invariant future marker plus the imperfect. Tosk and Aromanian are almost the same, but they still have the SP, at least optionally. MR has an invariant 'will' marker (*vrẹa*) + SP + present or perfect (see 'Perfect in "Have"'). In Bulgarian, Torlak, and other dialectal BCS, however, it is 'will' that conjugates in the imperfect+SP+present, and Gheg has the conjugated imperfect auxiliary 'have' + infinitive. The Balkan construction extends into BCS as far as southern Croatia and southwestern Serbia, and the southern Montenegrin dialects have the widest range of uses for the construction, thereby being most Balkan. In Turkish, the future participle plus a past auxiliary *[i]di* or [*i*]*miş* has the same nuances of irrealis conditional (Table 6).

In Greek, Albanian, and Vlah, conditional constructions normally have a form of the 'will' morpheme. In BS, the Balkan conditional is in competition with the inherited conditional using the old optative of 'be' (invariant *bi* in Macedonian, conjugating in Bulgarian and Torlak) + old resultative participle. Romani dialects in contact with Slavic also use invariant *bi* + present as a conditional. In Romanian, a special conjugation of 'have' + infinitive serves as a conditional-optative.

Table 6 The Balkan conditionals

Romani	ka		keravas*
Greek	thá		égrafa
Macedonian	ḱe		napravev^{u}
Aromanian	va	[s]	făceam^{u}
Albanian (Tosk)	do	të	bëja
	FU	*SP*	*do.IM.ISG*
MR	vrẹa	si	am fat(ã)
	want.PRES.3SG	SU	do.PERF.1SG
Bulgarian	štjah	da	napravja
	šćaše/šćeše	da	napravim/ radim
	want.3SG.IM	*SU*	*do.PRES.1SG*
Albanian (Gheg)	[kishna	me	bâ]
	I.have	*with*	*do.PART*
Romanian	aș	fi	făcut
	COND	*be.INF*	*do.PAST.PART*
Turkish	yap	acak	tı m
	ROOT	*FU*	*PAST 1SG*
'I would have done'			

*Arli has a new imperfect formed by the long present + imperfect of '3SG/PLbe', e.g. *kerava sine*.

Perfect in 'Have' The use of 'have' as an auxiliary with a nonfinite main verb to form an analytic perfect is attested for Greek and Latin at the end of the ancient period and is characteristic of Albanian, BR, and Greek, while such constructions (and lexical 'have') are absent from WRT and most of Romani. In BS 'have' + past passive participle (or its descendant) forms resultative constructions ranging from a fully grammaticalized perfect (with an invariant neuter verbal adjective) that has completely replaced the inherited perfect ('be' + old resultative particle in *-l*) in extreme southwestern Macedonian and spreading north to Mt. Šar and east to the Vardar and beyond, to resultative syntagms with 'have' + past passive participles agreeing with their direct objects and limited to transitive verbs with human subjects in most of Bulgaria.

Given the geography and history of the 'have' perfect in BS, it is clearly a calque on one of the non-Slavic contact languages. Although Greek and Albanian have been proposed as the possible models, Gołąb's arguments in favor of Aromanian are the most convincing. In Aromanian, the feminine participle is selected as the invariant, since in BR (as in Albanian) the feminine gender is unmarked (neuter is obsolete). The Macedonian invariant neuter verbal adjective therefore corresponds exactly to the Aromanian in terms of unmarked gender. In Greek, the main verb is a remnant of the infinitive and in Albanian the participle does not mark singular gender. Thus the BR construction most closely resembles the Macedonian. An additional argument in favor of BR as the model is evidence of Macedonian and Vlah mutual calquing in other resultative constructions.

Table 7 Aromanian (Fărshălots, Bela di Suprã and Albanian indicatives (3sg 'work')

	Nonadmirative		*Admirative*

2nd Dbl. plup.	avu avut lukratã	pat pasë punuar	–	–

Table 8 The Novo Selo probabilitive 'see'

Present	1	gla*dàčă m	gla*dàčă mo
	2	gla*dàčăš	gla*dàčă tă
	3	gla*dàčă	gla*dàčă ju
Future		că gla*dàčă m, etc.	
Past		budàčă m ∼ bičă m glă dàl, etc.	

Evidential In a Balkan context, evidentiality (inferential, distance, mode of indirect narration, indirective, status, French *médiatif*) is a grammatical category encoding the speaker's evaluation of the narrated event, often, but not always, predicated upon the nature of the available evidence. Evidentials can be of two types: confirmative (vouched for, 'witnessed') and nonconfirmative (not vouched for, 'reported', 'inferential'). The nonconfirmative can be felicitous (neutral report or inference) or infelicitous, in which latter case the nonconfirmative expresses either acceptance of a previously unexpected state of affairs (i.e., surprise, admirativity *sensu stricto*) or rejection of a previous statement (i.e., sarcasm, dubitativity). The opposition confirmative/nonconfirmative was already encoded in the Turkic simple past in *-di* (confirmative) and the perfect participle in *-miş* (nonconfirmative) at the time of the earliest monuments. In East South Slavic, the old synthetic pasts are markedly confirmative (this same meaning is also sometimes identified in Torlak). By contrast, the old perfect using the resultative participle in *-l* has become an unmarked past, with a chief contextual variant meaning of nonconfirmative. In Albanian, the inverted perfect (participle + 'have') has fused into a marked nonconfirmative present paradigm called admirative, which can then function as an auxiliary to form analytic past tenses. The Frasheriote Aromanian dialect of Bela di Suprã has reinterpreted the 3SG.PRES Albanian admirative marker as an admirative suffix, which it adds to a masculine plural imperfect participial base to form a new admirative (Table 7).

Megleno-Romanian uses an inverted perfect + auxiliary construction in a similar function. The Romanian presumptive mood formed with a future, subjunctive, or conditional marker + invariant *fi* 'be' + gerund (or past participle) is a similar marked nonconfirmative, as is the probabilitive mood (based on a BCS-type inverted future) of Novo Selo Bulgarian, a dialect spoken across the Danube from Romania and a few kilometers east of Serbia (Table 8).

The Judezmo of Istanbul uses the pluperfect as a calque on the Turkish past in *-miş*:

Kuando esta-v-an en l' Amérika, les
when be-IM-3PL in the America them.DAT
av-iy-a entra-do ladrón
have-IM-3SG enter-PAST.PART thief
'When they were in America [i.e., absent], a thief broke into (Turkish *girmiş*) their house.'

Other Many other features too numerous to discuss here are cited as Balkanisms, e.g., the conflation of adverbs of location and motion ('where'/'whither'), purposives in 'for' + SP + verb and other prepositional parallelisms, a distinction between realis and irrealis complementizers, and absolute relativizers and interrogatives as complementizers, this last being a feature that has spread to WRT:

čovek-ot što go vid-ov (Macedonian)
person-the what him.ACC see-1SG.AOR
adam ne cür-d-üm (WRT)
man what saw-PAST-I
gör-düğ-üm adam (Standard Turkish)
see-PART-my man
'the man that I saw'

Word Order

Clitic Ordering Greek, Albanian, and BR all permit absolute initial pronominal clitics when the first stressed element is a finite verb, but in BS only Macedonian (especially the western dialects) permits this. Bulgarian keeps pronominal clitics bound to the verb

but either requires the verb or some other element in initial position. BCS, including most of Torlak, still follows Wackernagel's law and has clitics in second position.

Az	često	mu	go	davam.	(Bulgarian)
I	*often.*	*him.DAT*	*it.ACC*	*give.1SG.PRES*	
Ja	mu	ga	često	dajem.	(Serbian)
I	*him.DAT*	*it.ACC*	*often*	*give.1SG.PRES.*	

'I often give it to him'

Davam	mu	go	(Bulgarian)
give.1SG.PRES	*him.DAT*	*it.ACC*	
Mu	go	davam	(Macedonian)
him.DAT	*it.ACC*	*give.1SG.PRES*	

'I give it to him'

Romani pronominal clitics follow the verb. WRT is basically suffixal, like the rest of Turkish, and clitics always follow the stressed element, but elements that can be fused or separated are more likely to be separated and less likely to show vowel harmony in WRT.

Constituent Order Balkan languages are characterized by relatively free constituent order with certain patterns being favored for various types of syntactic and narrative strategies (emphasis, topicalization, focus, contrastive thematization, etc.). The unmarked word order tendency is SVO in all the Indo-European Balkan languages. Unlike most of Turkish, where the tendency is verb-final, WRT and Gagauz show SVO tendencies. Similarly, BR, BS, Albanian, and Greek all have the basic order head-genitive, while Turkish and Romani are genitive-head. Romani dialects in the Balkans and WRT, however, also have head-genitive constructions:

m-e	phral-es-k(er)e	kher-es-k(or)o	vudar	(Romani)
my-OBL	*brother-OBL-GEN*	*house-OBL-GEN*	*door*	

'the door of my brother's house'

o	vudar	e	kher-es-ko
the.MASC.NOM	*door*	*the.OBL*	*house–OBL-GEN*

m-e	phral-es-kere	(Romani)
my-OBL	*brother-OBL-GEN*	
Baba-si	Ali-nin	(WRT)
father-his	*A.-GEN*	
Tatkto	mu	na	Ali	(Macedonian)
father	*him.DAT*	*to*	*Ali*	
Baba-i	i	Ali-ut	(Albanian)
father-DEF	*PC.MASC.NOM.SG*	*A.-Def.GEN*	

Ali-nin	babası	(Standard Turkish)
Ali-GEN	*father-his*	

'Ali's father'

Adjectives generally follow their heads in Albanian and BR, but precede in BS, Greek, WRT, and Romani. In all of these languages, the opposite order is possible in various discourse functions. Albanian enclaves in the eastern Balkans also have preposed adjective as the standard order.

Lexicon, Semantics, and Derivational Morphology

The etymological commonalities of the Balkan lexicon received considerable attention during the formative years of Balkan linguistics, whereas more recently the focus has been on shared grammatical features. Miklosich's 1861 survey of Balkan grammatical commonalities occupied only 4% of what was basically a study of the Slavic lexical influence on Romanian. Sandfeld (1930) devotes 40% of his book to the lexicon, whereas Asenova (2002) allots 10% of her text to such issues. Although the lexicon is the most salient surface manifestation of linguistic influence, words can travel between languages without the aid of communal multilingualism, whereas the diffusion or convergence of grammatical structures is a more complex process that requires at least a core community of bi- or multilingual speakers. In terms of the definition of a sprachbund, it is the shared grammatical features rather than shared vocabulary that is the key determiner, although shared vocabulary is usually part of the picture.

There are common loanwords from each of the component language families in the Balkan languages. Words shared by Albanian and Romanian of pre-Latin (substrate) origin are often connected with domestic items or husbandry, e.g., Albanian *shtrungë*, BR *strungă*, BS (Macedonian and west Bulgarian) *strunga*, Greek (Epirus and Sarakatsan) *stroúgka* 'dairy'. Greek, Slavic, and Romance (especially Balkan Latin and Venetian Italian) were all languages of power in the Balkans at various times during the Middle Ages and contributed a variety of lexemes and even derivational affixes to the common Balkan lexicon, e.g., the Latin agentive suffix *-arius*, the Slavic feminine suffix *-ica* , and the Greek aorist marker *-s-* (used in deriving verbs). As the language of administration, the market place, and urban life in general, Turkish dominated the Balkan peninsula for more than half a millennium. By the 19th century, the shared Turkish lexicon in the Balkan languages was of considerable size. The rise of Balkan standard languages, however, entailed the stylistic lowering and marginalization of many Turkish loanwords, and as many of these items were of Arabo-Persian origin, they were discouraged by Turkish purists as well. The Turkish agentive *-ci*, attributive *-li*, qualitative or concrete *-lik* (with adjustments for vowel harmony, voicing assimilation, and adaptation) continue to be productive as derivational affixes, e.g., Macedonian *pubertetlija* 'adolescent (ironic)' Albanian *partiakçi* 'party hack', Judezmo *hanukalik* 'Chanukah present', etc.

The Balkan languages also share numerous idioms, collocations, and calqued expressions; e.g., the use of 'eat' to mean 'undergo something unpleasant' as in 'eat wood' = 'take a beating' or 'it doesn't cut his mind' = 'he doesn't understand'. There are a variety of shared discourse particles and conjunctions (e.g., Turkish *am[m]a* 'but', Greek *bre* 'hey, vocative particle') that also form part of the common Balkan lexicon.

Figure 1 Schematic linguistic social/political hierarchy (Ottoman Period).

Sociolinguistics

Factors such as power, prestige and religion have influenced directions and degrees of Balkan contact phenomena. Throughout the Ottoman period, Turkish had high prestige as the language of the state and the town, Greek had prestige among Christians as the language of the (Orthodox) church with its own literary tradition (and history of power, i.e., Byzantium) and was also a language of commerce. BS had less prestige in the southern Balkans, but its history of medieval literacy and political competition with Byzantium gave it some limited prestige. Although BR was descended from Latin, another language of empire and conquest, the local varieties that developed after the Slavic invasions did not have that level of prestige and, like Albanian, were associated mainly with rural contexts. In Wallachia and Moldavia, Church Slavonic was the liturgical language for centuries, and Romanian was written in Cyrillic until the mid-19th century. Aromanian speakers in southern Balkan towns used Greek outside the home. Romani was at the bottom of the social hierarchy, but Judezmo was outside it. This is reflected in 19th-century Macedonian folklore collections, where characters in ethnic jokes, including Roms (Gypsies), speak in their own languages, except Jews, who speak Turkish, not Judezmo. For both Romani and Judezmo, multilingualism was unidirectional, i.e., Roms and Jews learned other languages but heard their languages spoken by others rarely, if ever. At the opposite end of the prestige scale, speakers of Greek and Turkish were less likely to learn less prestigious languages but were more likely to hear their languages spoken by others. Those languages in the middle of the hierarchy (BS, BR, and Albanian) had the highest degree of multidirectional multilingualism and show a higher degree of congruence.

Marriages could be freely contracted across linguistic lines but not religious ones, so that multilingual households were a commonplace. Although speakers of BS, BR, and Greek were mostly Christian and speakers of Albanian were usually Muslim, each of these religions also had significant communities speaking the other languages. Except for Gagauz, speakers of Turkish were Muslim, but there was still plenty of linguistic contact via religious conversion. Jews and Roms, however, were endogamous along a combination of linguistic and other social lines. This boundary maintenance is reflected linguistically in Romani, where there is a clear opposition between the relatively open systems of adjectival comparison and modality on the one hand to the conservative nominal, pronominal, and tense-aspect systems on the other.

Figure 1 illustrates the relative prestige of the various languages during the Ottoman period. Height symbolizes prestige, while incline indicates relative (never absolute) directionality. The directionality is reversed in the case of slang and secret languages, where it is the covert prestige of languages further down on the social scale that is reflected in patterns of lexical borrowing. In the case of Judezmo, knowledge of Turkish was most widespread, while knowledge of other Balkan languages would depend on the particular (urban) environment.

Causation

For most of the history of Balkan linguistics, causation has been sought in the influence of (interference from) one of the languages, e.g., Greek, Latin, or a pre-Latin non-Hellenic substratum (e.g., Illyrian, Thracian, and/or Dacian – all so poorly attested that we do not have so much as a single sentence in any of them). More recently, however, an ecological model of feature selection argues that those grammatical developments more suitable for effective communication that might be already present in the language, i.e., more adaptive, are more likely to be selected for further development and spread (cf. 'Resumptive Clitic Pronouns [Reduplication, Replication]'). In such a model, languages can utilize native resources that are reinforced by their occurrence, or potential for occurrence, in the contact languages. Mechanisms such as fusion, metatypy, and code copying are all potentially relevant. At the same time, sociolinguistic factors such as those adduced in 'Sociolinguistics' can

influence directions of change. The diffusion of borrowings and the development of convergences are thus compatible parts of a larger picture of a sprachbund in which languages come to be similar without becoming identical. It is worth emphasizing here the insight of Joseph (2001), namely that the move from lexical via phraseological to syntactic borrowings that characterizes the contact-induced changes of a sprachbund such as the Balkans are quintessentially surface phenomena.

Although some scholars have argued against the idea of a Balkan sprachbund since the 1930s, the argument that the Balkans are basically just part of a larger European linguistic zone coincides roughly with the recent rise in interest in contact linguistics and typology. In the case of the Balkans, however, while it is clear that Kopitar's formulation is an exaggeration, it is equally clear that Trubetzkoy's original insight captures facts about language relationships. Of particular significance is the manner in which patterns map such that the languages that surround the Balkan sprachbund do not share the most salient features. The fact that English and Western Romance have gone even further than most of the Balkan languages in some changes does not contradict the hypothesis that the Balkan sprachbund is precisely that, i.e., a product of the process of language contact. If some of those contact-induced changes are the result of shared feature selections, having parallels elsewhere, that may contribute to identifying likely directions of language change, but it does not vitiate the sprachbund as a historical and sociolinguistic phenomenon.

In a sense, a sprachbund is more like a dialect chain than a linguistic family: as features spread over areas, they may do so with differential impact. Thus, while it is possible to define a sprachbund in terms of languages displaying a coalescence of a number of such features, it is not necessarily the case of an 'all and only' phenomenon. Moreover, the transition from pragmatic to syntactic (grammaticalized) to morphological sometimes maps onto the territory of the sprachbund itself, moving from periphery to core. Like dialects, there can be a transitional effect, and a given language, e.g., BCS, can participate in the changes to a greater or a lesser extent. For both the dialect and the sprachbund, politics can have a crucial effect in setting boundaries that favor internal consistency and external differentiation. Just as the very concept of language vis-à-vis dialect (e.g., to which language a given dialect 'belongs' or which isoglosses will be chosen as defining one dialect in opposition to another) can be a complex of intersecting factors, so too can the definition of sprachbund.

Balochi

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Balochi (or Baluchi, in several dialects) is spoken by the Baloch in eastern Iran and western Pakistan (Baluchistan), but also in southern Afghanistan, Turkmenistan, and the Arab Gulf States (totaling 6–8 million speakers?). The Baloch are first mentioned in literature about 1000 C.E., but the language did not become a written one until the 20th century, although the earliest known manuscript dates from the early 19th century. On the other hand, the Baloch have an oral poetic tradition with historical themes reaching back to the 15th century, but especially productive in the 19th century. Modern literature and publications are centered in Quetta in Pakistani Baluchistan and in Karachi. A Balochi Academy was founded in Quetta in 1959 and still publishes Balochi literature and supports Balochi language and culture in various ways, and the University of Quetta offers a Balochi Studies program. Balochi radio programs are broadcast from Zahedan in Iranian Balochistan and from Quetta and Karachi, formerly also from Kabul.

There are, by one count, six principal dialects of Balochi, characterized by differences in grammar and lexicon. The western dialect of Raxšānī is the largest, the principal subdialect being Sarhaddī,

Balochi belongs with the North(west) Iranian languages, differently from Persian, which is a Southwest Iranian language; compare, for instance, Balochi *asin* 'iron,' *ǰan-* [dʒan-] 'strike,' *zird* 'heart,' versus Persian *āhan*, *zan-*, *dil*. It is a phonetically conservative language, having preserved much of the Old Iranian consonant system intact, notably intervocalic stops and affricates, for instance, Bal. *pād* 'foot,' *āp* 'water,' *roč* [rōtʃ] 'day' (Pers. *pā*, *āb*, *rūz*). Among innovations are the development of initial *w-* to *g(w)* (OIran. *wāta-* 'wind,' Bal. *gwāt*, Pers. *bād*), *xw-* to *w-* (OIran. *xwara-* 'eat,' Bal. *war-*, Pers. *x*^{v}*or-*), and the change of fricatives into stops (Bal. *nākun* 'nail,' Pers. *nāxon*; Bal. *gipta* 'seized,' Pers. *gereft*).

Balochi has retroflex consonants in words borrowed from Indo–Aryan, including originally English words, for instance, *ḍrēwar* (*ḍ* = [ɖ]) 'driver.'

Balochi

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Balochi (or Baluchi, in several dialects) is spoken by the Baloch in eastern Iran and western Pakistan (Baluchistan), but also in southern Afghanistan, Turkmenistan, and the Arab Gulf States (totaling 6–8 million speakers?). The Baloch are first mentioned in literature about 1000 C.E., but the language did not become a written one until the 20th century, although the earliest known manuscript dates from the early 19th century. On the other hand, the Baloch have an oral poetic tradition with historical themes reaching back to the 15th century, but especially productive in the 19th century. Modern literature and publications are centered in Quetta in Pakistani Baluchistan and in Karachi. A Balochi Academy was founded in Quetta in 1959 and still publishes Balochi literature and supports Balochi language and culture in various ways, and the University of Quetta offers a Balochi Studies program. Balochi radio programs are broadcast from Zahedan in Iranian Balochistan and from Quetta and Karachi, formerly also from Kabul.

There are, by one count, six principal dialects of Balochi, characterized by differences in grammar and lexicon. The western dialect of Raxšānī is the largest, the principal subdialect being Sarhaddī,

Balochi belongs with the North(west) Iranian languages, differently from Persian, which is a Southwest Iranian language; compare, for instance, Balochi *asin* 'iron,' *ǰan-* [dʒan-] 'strike,' *zird* 'heart,' versus Persian *āhan*, *zan-*, *dil*. It is a phonetically conservative language, having preserved much of the Old Iranian consonant system intact, notably intervocalic stops and affricates, for instance, Bal. *pād* 'foot,' *āp* 'water,' *roč* [rōtʃ] 'day' (Pers. *pā*, *āb*, *rūz*). Among innovations are the development of initial *w-* to *g(w)* (OIran. *wāta-* 'wind,' Bal. *gwāt*, Pers. *bād*), *xw-* to *w-* (OIran. *xwara-* 'eat,' Bal. *war-*, Pers. *x*ᵛ*or-*), and the change of fricatives into stops (Bal. *nākun* 'nail,' Pers. *nāxon*; Bal. *gipta* 'seized,' Pers. *gereft*).

Balochi has retroflex consonants in words borrowed from Indo–Aryan, including originally English words, for instance, *ḍrēwar* (*ḍ* = [ɖ]) 'driver.'

There is a four-case system, distinguishing nominative, genitive, and an oblique case. The suffix *-rā* (*-ā* with personal pronouns) can be added to the oblique to express direct and indirect objects.

Notable features of the verb system include the formation of continuous tenses by means of a present participle in *-ag* (*raw-ag-ā int* 'go-ing-in he-is' = 'he is going'), a construction perhaps influenced by the neighboring Indic languages and replacing the older formation with prefix *a-* (*a-rot* 'he goes, is going'). In the conservative dialects, the past tenses use the ergative construction in pure passive form (*man gūnī zurt-ant o šut-un* 'I.OBL sack.PL take.PAST-3RD.PL and go.PAST-1ST SING' = 'I took the sacks and went'), while in the western dialects, the active construction of Persian prevails (*man gūnī-ān zurt-un o šut-un* 'I.DIR/OBL sack.PL.DO take.PAST-1ST.SING and go.PAST-1ST.SING' = 'I sacks took-I and went-I').

Balochi lexicon contains a large number of loanwords, mainly Arabo–Persian and Indo–Aryan from a western Sindhi dialect, as well as a small number of words from Brahui, a Dravidian language, which contains a large number of Balochi words.

Balto-Slavic Languages

S Young, University of Maryland Baltimore County, Baltimore, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

The term Balto-Slavic encompasses the languages of the closely related Baltic and Slavic branches of the Indo-European language family. The Slavic languages, traditionally divided into East, West, and South Slavic, are well-represented over much of Central and Eastern Europe and Siberia. Of the once more numerous and widespread Baltic languages, only two have survived to the present, Latvian and Lithuanian, which together form East Baltic. West Baltic is represented by Old Prussian, which died out in the early 18th century; it is known from word lists, place names, and catechism translations.

The nature of the relationship between the Baltic and Slavic languages has long been a source of debate. In the traditional *Stammbaum* approach, reflected in K. Brugmann's landmark *Grundriß der vergleichenden Grammatik der indogermanischen Sprachen,* Baltic and Slavic are presented as equivalent branches of a Balto-Slavic protolanguage, which derives in turn from Proto-Indo-European.

The assumption of a post-Indo-European period of Balto-Slavic linguistic unity is based on a number of striking and seemingly exclusive correspondences between the Baltic and Slavic languages. In phonology, the most cogent argument for a Balto-Slavic protolanguage is found in the highly complex prosodic structures of both language families, which typically agree in details of stress placement (including reflexes of Hirt's law), syllable tone (including reflexes of Winter's law), and accentual paradigm. Among other phonological agreements, syllabic resonants develop into both *-iR-* and (exceptionally) *-uR-,* with a similar distribution in both language groups. Morphological correspondences include an *-ā* formant marking the preterite/aorist stem, often accompanied by the reduced grade of the root: Lith. *pĩrko* (pres. *peřka*) 'buy.PRET' : OCS *žьda* (pres. *židetь)* 'wait, expect.AOR'; and a present passive participle in *-m-* (for East Baltic and Slavic): Lith. *nešamas,* Latv. *nesams* : OCS *nesomъ* 'being carried'. There are a number of exclusive correspondences in word formation, among them deverbal nouns in-*imo-:* Lith. *piešìmas* 'drawing' : Slavic **pisьmo* 'writing'; agent nouns in *-ā-i̯o-:* Lith. *artójus*, OPr. *artoys :* OCS *ratajь* 'plowman'; agent nouns in *-ik-o*: Lith. *siuvìkas*, OPr. *schuwikis* 'shoemaker' : ORus. *šьvьcь* 'tailor; shoemaker'; denominal adjectives in *-in-:* Lith. *krùvinas* : OSC *krъvьnъ* 'bloody', and diminutives in *-uk-o-*: Latv. *dę̄luks*, OCS *synъkъ* 'sonny'. Finally, there are

There is a four-case system, distinguishing nominative, genitive, and an oblique case. The suffix *-rā* (*-ā* with personal pronouns) can be added to the oblique to express direct and indirect objects.

Balto-Slavic Languages

S Young, University of Maryland Baltimore County, Baltimore, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

The term Balto-Slavic encompasses the languages of the closely related Baltic and Slavic branches of the Indo-European language family. The Slavic languages, traditionally divided into East, West, and South Slavic, are well-represented over much of Central and Eastern Europe and Siberia. Of the once more numerous and widespread Baltic languages, only two have survived to the present, Latvian and Lithuanian, which together form East Baltic. West Baltic is represented by Old Prussian, which died out in the early 18th century; it is known from word lists, place names, and catechism translations.

The nature of the relationship between the Baltic and Slavic languages has long been a source of debate. In the traditional *Stammbaum* approach, reflected in K. Brugmann's landmark *Grundriß der vergleichenden Grammatik der indogermanischen Sprachen,* Baltic and Slavic are presented as equivalent branches of a Balto-Slavic protolanguage, which derives in turn from Proto-Indo-European.

The assumption of a post-Indo-European period of Balto-Slavic linguistic unity is based on a number of striking and seemingly exclusive correspondences between the Baltic and Slavic languages. In phonology, the most cogent argument for a Balto-Slavic protolanguage is found in the highly complex prosodic structures of both language families, which typically agree in details of stress placement (including reflexes of Hirt's law), syllable tone (including reflexes of Winter's law), and accentual paradigm. Among other phonological agreements, syllabic resonants develop into both *-iR-* and (exceptionally) *-uR-,* with a similar distribution in both language groups. Morphological correspondences include an *-ā* formant marking the preterite/aorist stem, often accompanied by the reduced grade of the root: Lith. *pĩrko* (pres. *peřka*) 'buy.PRET' : OCS *žьda* (pres. *židetь)* 'wait, expect.AOR'; and a present passive participle in *-m-* (for East Baltic and Slavic): Lith. *nešamas,* Latv. *nesams* : OCS *nesomъ* 'being carried'. There are a number of exclusive correspondences in word formation, among them deverbal nouns in-*imo-:* Lith. *piešìmas* 'drawing' : Slavic **pisьmo* 'writing'; agent nouns in *-ā-i̯o-:* Lith. *artójus*, OPr. *artoys :* OCS *ratajь* 'plowman'; agent nouns in *-ik-o*: Lith. *siuvìkas*, OPr. *schuwikis* 'shoemaker' : ORus. *šьvьcь* 'tailor; shoemaker'; denominal adjectives in *-in-:* Lith. *krùvinas* : OSC *krъvьnъ* 'bloody', and diminutives in *-uk-o-*: Latv. *dę̃luks*, OCS *synъkъ* 'sonny'. Finally, there are

many apparently exclusive lexical items, among them Lith. *rankà* : OCS *rǫka* 'hand'; Lith. *rãgas* : OCS *rogъ* 'horn'; Lith. *líepa* : OCS *lipa* 'linden'.

The assumption of a Balto-Slavic proto-language was first challenged by A. Meillet (1908), who argued that the various agreements between the two language families are only apparent, a result of inherited archaisms and parallel developments in each of the branches. A refinement of this model was advanced by J. Endzelin (1911), who accounted for shared features by positing a period of prolonged language contact between neighboring Baltic and Slavic communities, leading to a degree of linguistic convergence.

More recent studies have stressed the non-equivalence of the notions of Baltic and Slavic. C. Stang (1966: 10 ff.), developing one of Endzelin's ideas, pointed out that while Common Slavic presents a relatively uniform system, Baltic is divided by a number of significant isoglosses. Certain of the innovations represented by these isoglosses connect East Baltic with Slavic as opposed to Old Prussian (for example, the Indo-European **-s(i̯)o* genitive singular of *o*-stem nouns, apparently preserved in Old Prussian, has been replaced in East Baltic and in Slavic by a form that appears outside of Balto-Slavic in ablative function: Lith. *rãgo*, Latv. *raga* = OCS *roga*, 'horn.-GEN SG'); while other isoglosses link Old Prussian with Slavic (for example, the possessive pronouns OPr. *mais, twais, swais* = OCS *mojь, tvojь, svojь* 'my, your, one's own' are refashionings of the IE root represented in Lith. *(manas), tavas, savas* and Latvian *(mans), tavs, savs*).

V. V. Ivanov and V. N. Toporov (1961), in reviewing the methodological preconditions for discussing the Balto-Slavic relationship, have argued that a relatively homogeneous proto-Slavic can be derived from a considerably more archaic and heterogeneous proto-Baltic linguistic model, in effect redefining the notion of Balto-Slavic by treating Slavic as a local development within a Baltic dialectal continuum.

Progress in further defining the relationship between Baltic and Slavic is hampered by a lack of linguistic data from the former Baltic populations assimilated by the East Slavs in the upper Dniepr river basin (the Dniepr Balts), and in present-day Baltic territories by neighboring Latvians and Lithuanians (the Couronians, Selians, Zemgalians, and Jatvingians). The written documents of extinct Old Prussian are scant and rather unreliable, while the earliest monuments of Latvian and Lithuanian date only from the 16th century, when these languages already had a modern appearance. Nevertheless, dialectal data (including toponymic) still being drawn from various Baltic and Slavic languages, together with a more profound study of Baltic and Slavic borrowings in neighboring languages, may help provide new perspectives on the question of Balto-Slavic.

Bamgbose, Ayo (b. 1932)

A Ojo, University of Georgia, Athens, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

Born Ayorinde Bamgbose on January 27, 1932, in Nigeria, Ayo Bamgbose is one of the most renowned African linguists. He attended St. Andrew's College, Oyo, Nigeria (1948 to 1951). With his teaching diploma, Bamgbose taught for six years in primary and secondary schools as well as teacher training college. In 1957, he enrolled at the University of Ibadan, Nigeria, and obtained a Bachelor of Arts degree in English with honors in 1960. Afterward, he proceeded to the University of Edinburgh, UK, for

his graduate work. He received a diploma in General Linguistics in 1961 and was awarded a doctorate in Linguistics in 1963 for his pioneering study of Yoruba grammar. His dissertation, 'A study of structures and classes in the grammar of modern Yoruba,' was the first ever written on Yoruba grammar. Upon his return to Nigeria in 1963, Bamgbose joined the department of Linguistics and Nigerian Languages as a lecturer and became a senior lecturer in 1966. He was appointed Professor of Linguistics and Nigerian Languages in 1968.

Professor Ayo Bamgbose has committed most of his teaching and research efforts on the study of Linguistics and Nigerian languages. He has worked extensively on Yoruba language with limited work on other Nigerian languages such as Mbe, Hausa, and Igbo. He is an internationally acclaimed scholar and teacher. He has served as a visiting professor at the University of Illinois, Urbana-Champaign (1978; 1993–1995), Hamburg University, Germany (1979–1980) and a visiting fellow at Clare Hall, Cambridge University, UK (1987–1988). More recently, Professor Bamgbose served as a visiting professor again at Urbana-Champaign from 1993 till 1995. From 1997 to 1999, he was a visiting professor at the University of Leipzig, Germany. He has also served as guest lecturer at several universities in Africa, Europe, and America. He became a professor emeritus for linguistics and African languages at the University of Ibadan, Nigeria, in 1994.

At the University of Ibadan, Professor Bamgbose has supervised numerous theses and dissertations by students who have gone on to become outstanding scholars and professors in linguistics and the study of African languages. He has also served administratively as, among others, Chair of the department of Linguistics and African languages, Dean of the Faculty of Arts, and Chair of the University Senate committees on Publications and the General Studies Program. He has served as an external examiner to many West African universities (Lagos, Ife, Ilorin, Legon, Sierra Leone, Yaounde, and Zimbabwe). Professor Bamgbose has also variously served outside the ivory tower. From 1966 to 1969, he was a member of the Western Nigeria Ministry of Education Committee on Yoruba orthography. He was a member and later Chairman of the National Language Centre Working Committee from 1968 to 1979. He served as the consultant linguist on the Center's projects. In 1991, he became the chairman of the working committee for the National Institute for Nigerian Languages.

Internationally, he is an ex-president of the West African Linguistic Society and the Yoruba Studies Association. He is a foundation member of the Linguistic Association of Nigeria. He served as a consultant to the Ford Foundation on language related projects from 1966 to 1973. Since 1971, he has served as language expert at several UNESCO conferences and at international conferences organized by organizations such as the British Council, the Ghana English Studies Association, and the World Congress of African Linguistics. He was one of the four directors of the Languages in Contact and Conflicts in Africa (LiCCA) project and is a current executive committee member of the Permanent International Committee of Linguistics (CIPL).

His research interests and publications are in five specific areas: Language and Linguistics, Language and Education, Curriculum Development, Adult Literacy, and Literature and Culture. His work in the area of language and linguistics has ranged from descriptive studies of Nigerian languages to applied linguistic research involving orthographies and language policy and planning as well as aspects of developing and teaching English as a second language in Nigeria. In the area of language and education, Professor Bamgbose has focused on the use of African languages as media of instruction and as subject matter in the curriculum. He has examined, among other things, problems of assessment of different practices, the problem of media transition, and the effective strategies for ensuring viable results in mother tongue education. His work in the third area of curriculum development has been geared to developing language materials for teaching diverse topics. Specifically in this area, he has worked to develop technical terminology in some Nigerian languages for the teaching of mathematics and the basic sciences at the elementary level. Even at the higher level, this same vision has aided Professor Bamgbose's collaborative work with other Yoruba scholars that produced the Yoruba Metalanguage with terminologies for teaching language, literature, and methodology in Yoruba.

In his fourth area of research interest, adult literacy, Professor Bamgbose has worked to design viable language materials using a flexible approach that allows the use of several local languages in adult literacy. Literature and culture is his fifth area of research interest and here, he studies aspects of Yoruba oral and written literature in the total context of Yoruba culture. His work has included the analysis of Yoruba proverbs and folktales as well as the comprehensive analysis of the novels of D. O. Fagunwa, one of the pioneer Yoruba writers. In the context of globalization along with the impact of foreign cultures and technology, Professor Bamgbose has worked on how the media are coping with the expression of foreign concepts in local Nigerian languages such as Yoruba. This newfound interest

brought about an interest in the study of language treatment and the teaching of Yoruba and other Nigerian languages as second languages.

Bangladesh is divided into six divisions, with 64 districts and 68 000 villages. After partition, on independence from Britain in 1947, Pakistan made Urdu the state language for both West Pakistan and East Pakistan (now Bangladesh), with the aim of unifying the country. This, in effect, instigated the Bangla Language Movement, which was a major factor in the Civil War in 1970 and led to the creation of Bangladesh as an independent country in 1971. Bengali (*see* **Bengali**) was declared to be the national language. It is the mother tongue of 90% of the people of Bangladesh and has a variety of dialects.

In 1995, it was officially announced that Bengali should be used for all official purposes. English is used, however, for international communication in business, aid, politics, and higher education, not only with Western countries but also within South Asia. School education is conducted in Bengali and Bengali is predominant in mass media. The main dialects of Bangladesh can be divided into four groups, East Bengali (subdialects Hajong, Sylheti, transitional, and Noakhali and Chittagong), Barendri (northern dialects), Kamrupi (Rajbansi-Bahe), and tribal languages. The 30 tribal languages are spoken by approximately 300 000 people.

East Bengali Dialects

The eastern, east central, southeastern, and southwestern subdialects of East Bengali have important phonological and morphological features. Variations of East Bengali are spoken in Greater Dhaka, Mymensingh, Barisal, and eastern parts of Faridpur.

Phonological Features

Nasals are absent, but a 'half-nasal' construction (vowel-nasal-consonant) is found with or without omission of the consonant following the nasal (e.g., *cand*, *can* 'moon'). Palatals are replaced by dento-palatal affricates such as /ts/ and /dz/ (and they sometimes merge with /s/ and /z/); examples are *tsan* 'moon' and *asil* 'was' (for Standard Colloquial Bengali) and *can* and *chilo*, respectively. Voiceless (aspirated) forms are frequently lost intervocally (e.g., *kaha* for *kaka* 'uncle' and *tohɔn* for *tokhɔn* 'then'). Sibilants turn to *h*, as in *bɔho* for *bɔso* 'sit' and *hala* for *sala* 'wife's brother.' Epenthesis is realized

brought about an interest in the study of language treatment and the teaching of Yoruba and other Nigerian languages as second languages.

Bangladesh is divided into six divisions, with 64 districts and 68 000 villages. After partition, on independence from Britain in 1947, Pakistan made Urdu the state language for both West Pakistan and East Pakistan (now Bangladesh), with the aim of unifying the country. This, in effect, instigated the Bangla Language Movement, which was a major factor in the Civil War in 1970 and led to the creation of Bangladesh as an independent country in 1971. Bengali (*see* **Bengali**) was declared to be the national language. It is the mother tongue of 90% of the people of Bangladesh and has a variety of dialects.

In 1995, it was officially announced that Bengali should be used for all official purposes. English is used, however, for international communication in business, aid, politics, and higher education, not only with Western countries but also within South Asia. School education is conducted in Bengali and Bengali is predominant in mass media. The main dialects of Bangladesh can be divided into four groups, East Bengali (subdialects Hajong, Sylheti, transitional, and Noakhali and Chittagong), Barendri (northern dialects), Kamrupi (Rajbansi-Bahe), and tribal languages. The 30 tribal languages are spoken by approximately 300 000 people.

East Bengali Dialects

The eastern, east central, southeastern, and southwestern subdialects of East Bengali have important phonological and morphological features. Variations of East Bengali are spoken in Greater Dhaka, Mymensingh, Barisal, and eastern parts of Faridpur.

Phonological Features

Nasals are absent, but a 'half-nasal' construction (vowel-nasal-consonant) is found with or without omission of the consonant following the nasal (e.g., *cand*, *can* 'moon'). Palatals are replaced by dento-palatal affricates such as /ts/ and /dz/ (and they sometimes merge with /s/ and /z/); examples are *tsan* 'moon' and *asil* 'was' (for Standard Colloquial Bengali) and *can* and *chilo*, respectively. Voiceless (aspirated) forms are frequently lost intervocally (e.g., *kaha* for *kaka* 'uncle' and *tohɔn* for *tokhɔn* 'then'). Sibilants turn to *h*, as in *bɔho* for *bɔso* 'sit' and *hala* for *sala* 'wife's brother.' Epenthesis is realized

in *rait* for *rati* or *ratri* 'night' and *buira* for *buro* 'old' in West Bengal, and is also realized with a short glide (from Rajshahi down to Satkhira, Sundarban) in the south (*baykko* for *bakko* 'sentence'). Some of these features are also common in other dialects throughout Bangladesh.

Morphological Features

Plural affixes are found as (*e*)*ra*, *-ain* (as in *beyTTain* 'women'), *-fait* (*beDi-fait* 'women'), and *gun, guli, gulin*, *gulain*; genitive plural forms are *go* and *-rar* (e.g., *amrar*, *amago* 'ours' and *ta-rar* 'theirs'). Case endings are *-e*/*æ* (NOM-SING); *-re*, *-rare*, *-ræ* (ACC-DAT); *-t* (LOC); and *-r*, (*r*)*ar*, (*e*)*rar, -gɔr* (GEN). There are three categories of tense markers. No *nu* past or present (perfect) forms are found, as in West Bengal, to form *korinu korechinu* 'I did,' but *l*-past is common. A preceding participle is used, as in *-khaiya gese* 'has eaten and gone,' or a verb form is used, followed by a participle, as in *-gæse giya* 'go, having gone.' The *b*-future takes the usual markers, but also shows *-m*/*um*/*mu* forms for first person only (e.g., *zam*, *zam-u*, 'I shall go' and *khe-l-um* 'I shall play'). It also has a form like *b* + *m*, as in *zai-b-am* and *khæl-bam*, and *-tam,* as in *zai-tam* 'I would go' (also 'to go'). Nonfinite forms are *kha-* + *ito* = *khaito* 'to eat,' *za* 'go' + *ito* = *zaito* 'to go,' and *kha* 'eat' + *iya* = *khaya* 'having taken food'; likewise, *zaiya* 'having gone' and *ne-* + *ite* > *nito* 'take'; *nito boilla* (double verb); alternatively, *loito*, *loiya* 'having taken.' Emphatic particles are added to verbs: *zaikoilam, gumai koilam*, or *zai-ga-oi*.

East Bengali Subdialects

Hajong Hajong is a mixed dialect with some original Tibeto-Burman forms. Variations are found in nominal forms. In conjugation, verbs take no number-person markers. Both dental and retroflex plosives are maintained. Some other groups at the foot of the Garo hills and in Sylhet border areas also use this speech form.

Easternmost East Bengali Subdialect (Sylheti) Phonological features are *o* > *u* as in *tumar* 'your' and *g'ura* for *ghora* 'horse'; *j* > *z*; in participles, *y* is not pronounced, as in *kori* for *koriya* 'having done'; locative case ends in *ɔ* (*g'ɔr-ɔ* 'in a house'); *p* > *pf* (not *f*); *-k* > *x*; *c*, *ch* > *s*; *h* > *O*; *n* is sometimes realized as retroflex *N*; aspiration is weakened; *kh* is similar to Arabic *kh*.

Morphological features are as follows: (1) case endings with object case *-re*; genitive *-ɔr*, locative *-tɔ* and *-o*; and ablative tone; (2) plural markers are *-ra*, *rar*, *rae*, and *-ain* (e.g., *ghɔr-ain* 'houses'); (3) verb forms have future tense *-bay*; verbal forms *dækh* 'to see' + *lay*, *-ɔin*, *bɔ* ('sit') + *ukka*; (4) pronominals are *tui* 'you' (inferior), *tain* 'he' (honorific), and *hæ* 'he' (ordinary); (5) southern verb forms are *hairam* 'I am eating' and *kha-r-in* 'he is eating'; and (6) northern verb forms are *khayar*, *khayt-ray*, *khay-ray*; and (inferior honorific) *khaita-soin*.

Southwestern Bengali Subdialects (Transitional) Southwestern dialects of Bangladesh along the West Bengal border in the southeast are also called 'transitional dialects.' These include the dialects of Kustia, Jhinaidaha, Jessore, Khulna, Satkhira, and also some areas of Western Faridpur. The vowel *o* is pronounced higher (*bun* for *bon* 'sister'). Infinitives take *i* for *e* (as in *nati* for *naite* 'to bathe') and shorten the verb. Kustia dialects resemble the Rarhi variety as found in Nadia and other places across the Indian border. Vowel harmony, retention of *s*, and *h* initially retained (but lost otherwise) are typical features.

Southeastern Bengali Subdialects (Noakhali and Chittagong) Southeastern Bengali dialects have distinct phonological features. An *R* is found in Noakhali (except in Feni) when preceded by a nasal vowel, as in *bã Ri* (also *ba-i* (dropping *-R-* intervocally and replacing the nasal vowel); *r* is found elsewhere, except in Kamrupi forms, in which it is omitted initially (*ram* > *am*). Development of spirants is used in place of *p*, *ph*, and *k* (in Sylhet and Chittagong, *x*, *f*; also a voiced counterpart of *x* in Chittagong, such as *gorir* 'I do' (< *kori-*), *xazi* (*kazi*), *xafɔr* (*kapor*)). Aspirated plosives turn to h and are also prone to elision (e.g., Standard Colloquial Bengali *ekhane* but Dhaka *ænɔ*). Nasalization is often found in the vicinity of a nasal sound or when the nasal is dropped (e.g., *ãi* for *ami* 'I', *ãr* for *amar* '*my,*' and *tɔ̃* for *tomar* 'your'). In Noakhali, nasalization is common in the vicinity of flapped *-r-* and voiced retroflex *d*, as in *OãDa* 'goat,' *gã Ri* 'coach', and *bã Ri* 'home'; spontaneous nasalization occurs, as in *hãsa* for *saccha* in Urdu-Hindi or *sotto* in West Bengali 'true'; forms such as *aponar* 'your' are realized as *amnEr*; thus, *agun* > *au:n* > *ɔ:n* 'fire.'

Morphological features of southeastern Bengali dialects are also distinct. The common pronominal questions are *kiya* for *ki* 'what,' *kiyare* 'for what,' and *-di* (Standard Colloquial Bengali *diye* 'by'). Noakhali *konDai* 'to where' and *thɔn* 'from' equals *kɔ̃De* and *tun* in Chittagong, respectively. Plural markers are *ɔ̃:l* and *ɔkkɔl*. Case endings differ only in the ending vowel, where *-e* is *æ* and *-er* is *-ɔr* (e.g., *ba-æ* for *bape* (NOM 'father' and *vaɔr* or *baθɔr* GEN 'of father'). Other features are similar to those of East Bengali dialects.

Barendri Northern Dialects

Dialects in the northern central part of Bangladesh also comprise the West Bengal variety, called Upper Rarhi and Barendri. Chapai Nowabgonj, Rajshahi, and the neighboring districts are the focal areas. These dialects have a number of peculiarities in common.

Phonological Features

Nasalization is retained (*e* > *æ*; *ɔ*, *O* > *u*); both *s* and *S* are used; *s* is prominent where Maldaha-Gouriya influence is conspicuous; *r* drops initially (*ruTi* > *uTi* 'bread') and an expansionic *r* is also found (e.g., *i:d* 'Muslim festival' > *ri:d*; *ɔsontos* > *rɔsɔntos* 'discontentment'). An *h* is retained and is sometimes inserted before checked syllables, but aspiration in voiceless stops is lost intervocally (e.g., *gamca* for g*amocha* 'towel') and finally (e.g., *sat* for *sathe* 'with' and *piT* for *piTh* 'back').

Morphological Features

Tense is realized as *kor-nu* 'I have done,' *kor-cu-nu* 'I was doing,' and *kor-mu* 'I shall do.' Future tense is realized as *-be* > *-pe* (*thak-pe* 'will remain') (*i*) *l*-past + first person *–am*, etc., or only *-il*. Case markers are *-k*, *-re*, *-rɔk* (ACC DET), *-thini* (ABL), and *-t* (LOC) as in *pachot* 'in the back.' Pronouns are *hami* 'I', *ui* 'he,' and *ɔra* 'they.' Plurals are formed with *-rɔk*, *-re*, and *-gulain* (as in *tumare jinis* 'your (PL) things' and *turek* 'by you' (PL)). According to S. S. Bose, the difference between Barendri and East Bengali dialects is almost nil in many aspects.

Kamrupi (Rajbansi-Bahe)

Additional northern dialects are the Kamrupi varieties in the Dinajpur, Rangpur, and Patgram-Kurigram-Nageswari regions. The Rajbansi variety is also found in the Darjeeling and Nepal regions, and there are claims that it is a separate speech form, like Assamese. Although it is influenced by Bangla grammar and vocabulary, it shows indications of Tibeto-Burman substrata. There are a number of Kamrupi peculiarities.

Phonological Features

In Kamrupi, *a* > *æ* (*potimæ* for *protima* 'god image') and *o* > *a*, *u* (*kon* > *kun* 'which,' *tomar* > *tumar* 'yours,' and *osukh* > *ɔsukh* 'disease'). Palato-affricates are realized as alveolo-palatals; *S* is retained, although *s* also occurs in some of the subvarieties. Initial aspiration in stop sounds is retained, epenthesis is mixed, and there is bimorism (*m*an*S*i for *manus* 'man' and *ɔgna* for *ɔgrɔhayɔn*, which is the word for a Bengali month.

Morphological Features

Past tense is realized as *-nu* (first person), *-li* (second person), and *-ilɔ* (third person); the future form (first person) is *-mu* (also *-im*). Pronominals are *m*∼*o*, *mui*, *ham*(*i*) 'I,' *amak* (oblique), and *hamra* (plural). Case endings are formed with *-t* (locative) and *-r*, *-k* (genitive). Plural markers are *-ra*, *-gula*, *gulak*, *gila*, and *-ghɔr*. Negative particles are used before verbs, as in *na jaõ* 'do not go.' Verbs take auxiliary particles as compounds (e.g., *ag khoa* for Standard Colloquial Bengali *rag kɔra*, *mɔnet khoa* for Standard Colloquial Bengali *mone laga*, and *hɔtaS khoa* for *hataṣ hɔwa*).

Tribal Languages

Bangladesh is a small country but has a large number of ethnic people. There are 35 or more ethnic groups that concentrate mostly in the Chittagong Hill Tracts, in the southeast, and a few others in the northern part of the country. The important groups in the Chittagong Hill Tracts include the Chakma, Marma, Murang, Mro, Khyang, Panko, Tripura, Urang, and Bawm. In the north (Rajshahi Division), there are the Rajbansi, Buna, Coach, Garo, Mhato, Munda, Saotal, and Uria groups. In Mymensingh and Northern Sylhet, there are the Hajong, Khasia, and Manipuri.

There are many bilinguals in the Chittagong Hill Tract area who use a variety of Burmese. The intertribal language is a local variety of the Chittagonian patois. In north and in Upper Sylhet, varieties of speech such as Garo mixed, Sylheti mixed, or a broken Bengali are found in an interlanguage situation. The Chakmas, Manipuries, and some other groups use a script of their own in addition to the Bengali script. The ethnic groups are keen to maintain their own languages, cultures, and religions.

Bantu Languages

D Nurse, Memorial University of Newfoundland, St. John's, NL, Canada

Introduction

Bantu is the largest of the dozen or so language families that make up the Niger-Congo phylum, which, with nearly 1500 languages, is the largest phylum in the world. Some 750 million people live in Africa, some 400 million speak a Niger-Congo language, and some 250 million – a third of all Africans – speak a Bantu language. Bantu-speaking communities live south of a line from western Cameroon across the Central African Republic, the Democratic Republic of Congo (DRC; once known as Zaire), Uganda, and northern Kenya to southern Somalia. Most languages spoken from that line to the southern tip of South Africa are Bantu. Within that area, they coexist with some non-Bantu languages: a few Khoisan, mostly in the southwest, a few Cushitic, in the northeast, and a string of Nilo-Saharan and Adamawa-Ubangian languages along and within the northern border. In all, 27 African countries – roughly a half – are partly or entirely Bantu speaking.

Certain generalities are true of Bantu-speaking communities. One is that, just as most African countries are multilingual, many individuals are bi- or multilingual. In former times, many who came in contact with neighboring communities, mainly males such as traders or soldiers, spoke two or more languages. Though this is still true, it is increasingly true that many young people are born into one language community, are formally educated in a second language, and may acquire a third language later. Men tend to speak more languages than do women, and living in cities encourages multilingualism more so than does life in rural areas (Wolff, 2000).

Another truism is that many languages are poorly described. Three broad language categories can be distinguished. At the lower end are many dozens of languages for which no data are available. In the middle, the largest set, are many languages for which some data are publicly available, ranging from just a word list to a partial description. Finally, for about 10% of the languages, a reasonably comprehensive grammar exists, as books, doctoral theses, or long articles. In some areas – for example, South and East Africa – the languages are fairly well described, whereas in others (Angola, Cameroon, the DRC, and Zambia) they are less well covered.

A third point concerns the poor health of some of these communities. Dividing the Bantu population of 250 million by the number of languages, 500, gives an average of half a million speakers per community, but that ignores the fact that many smaller communities, especially rural, are in much worse shape than the figures indicate. The best demographic collection available (Gordon, 2004) gives figures for most communities, but gives no breakdown according to age. In many small communities, the fluent speakers are aging, with few or no younger speakers, so these communities of speakers will silently fade away in this century. As the small communities get smaller, the large get larger. At the same time, new urban and regional forms of languages are thriving (*see* Sommer, 1992; Bernsten, 1998; Wolff, 2000).

Finally, across the area, it has proved difficult to distinguish language from dialect. The difference is one of degree of similarity, and the question concerns where to cut a cline of similarity. Thus readers should treat with skepticism the figure of 500 Bantu languages. Estimates have varied between 300 and 600. If lack of reasonable mutual intelligibility with other varieties is a major defining feature of a language, then the figure is nearer 250 than 500.

Classifications

The second half of the 20th century saw dozens of referential and genealogical classifications. The most widely used referential system is that of Guthrie (1948, 1971), who divided the (Narrow) Bantu languages into 15 zones (designated A, B, C, D, E, F, G,

Introduction

Bantu is the largest of the dozen or so language families that make up the Niger-Congo phylum, which, with nearly 1500 languages, is the largest phylum in the world. Some 750 million people live in Africa, some 400 million speak a Niger-Congo language, and some 250 million – a third of all Africans – speak a Bantu language. Bantu-speaking communities live south of a line from western Cameroon across the Central African Republic, the Democratic Republic of Congo (DRC; once known as Zaire), Uganda, and northern Kenya to southern Somalia. Most languages spoken from that line to the southern tip of South Africa are Bantu. Within that area, they coexist with some non-Bantu languages: a few Khoisan, mostly in the southwest, a few Cushitic, in the northeast, and a string of Nilo-Saharan and Adamawa-Ubangian languages along and within the northern border. In all, 27 African countries – roughly a half – are partly or entirely Bantu speaking.

Certain generalities are true of Bantu-speaking communities. One is that, just as most African countries are multilingual, many individuals are bi- or multilingual. In former times, many who came in contact with neighboring communities, mainly males such as traders or soldiers, spoke two or more languages. Though this is still true, it is increasingly true that many young people are born into one language community, are formally educated in a second language, and may acquire a third language later. Men tend to speak more languages than do women, and living in cities encourages multilingualism more so than does life in rural areas (Wolff, 2000).

Another truism is that many languages are poorly described. Three broad language categories can be distinguished. At the lower end are many dozens of languages for which no data are available. In the middle, the largest set, are many languages for which some data are publicly available, ranging from just a word list to a partial description. Finally, for about 10% of the languages, a reasonably comprehensive grammar exists, as books, doctoral theses, or long articles. In some areas – for example, South and East Africa – the languages are fairly well described, whereas in others (Angola, Cameroon, the DRC, and Zambia) they are less well covered.

A third point concerns the poor health of some of these communities. Dividing the Bantu population of 250 million by the number of languages, 500, gives an average of half a million speakers per community, but that ignores the fact that many smaller communities, especially rural, are in much worse shape than the figures indicate. The best demographic collection available (Gordon, 2004) gives figures for most communities, but gives no breakdown according to age. In many small communities, the fluent speakers are aging, with few or no younger speakers, so these communities of speakers will silently fade away in this century. As the small communities get smaller, the large get larger. At the same time, new urban and regional forms of languages are thriving (*see* Sommer, 1992; Bernsten, 1998; Wolff, 2000).

Finally, across the area, it has proved difficult to distinguish language from dialect. The difference is one of degree of similarity, and the question concerns where to cut a cline of similarity. Thus readers should treat with skepticism the figure of 500 Bantu languages. Estimates have varied between 300 and 600. If lack of reasonable mutual intelligibility with other varieties is a major defining feature of a language, then the figure is nearer 250 than 500.

Classifications

The second half of the 20th century saw dozens of referential and genealogical classifications. The most widely used referential system is that of Guthrie (1948, 1971), who divided the (Narrow) Bantu languages into 15 zones (designated A, B, C, D, E, F, G,

H, K, L, M, N, P, R, S), and each zone in turn into groups (designated A11, A12, A13,..., etc.), for a total of 85 groups. Thus Nen is A44, Lingala is C36(d), Ha is D66, varieties of Swahili are G41, -42, or -43, and Zulu is S42. Guthrie's zones and groups are based partly on shared features he regarded as important, and partly on geographical contiguity. The most recent version of Guthrie (2003) is Maho. Guthrie's taxonomy did not reflect history, except indirectly.

In contrast, genealogical classifications aim to reflect the evolutionary history and, to a lesser extent, the contact history of the Bantu languages. Nearly all genealogical classifications assume that the current languages derive from Proto-Bantu and nearly all are based on the use of vocabulary in some form: lexicostatistics (counting percentages of shared vocabulary), glottochronology (assigning dates to percentages of shared vocabulary), shared lexical innovations, or juxtaposing results from lexical investigations with those from other disciplines, such as culture or archaeology (DNA comparison on a wide scale is so far lacking). The only study that examined the whole Bantu area and drew on hundreds of languages was the lexicostatistical work of Bastin *et al.* (1999); others used a smaller sample (Ehret, 1998, 1999; Nurse, 1999; Nurse and Philippson, 2003; see also Nurse, 1994–1995). Most of these classifications have in common that (1) they have some trouble defining an exact line between Narrow Bantu and closely related Bantoid languages in Cameroon, (2) they see a small set of languages (zones A, B, C, and bits of D and H, spoken in the northwest and north, in Cameroon, Gabon, Congo, and the northern fringe of the DRC, often called the Forest languages) as different from the rest, and (3) they divide the rest, the majority, into a smaller western (Angola, Namibia, parts of the DRC, Zambia, and Botswana) and a larger eastern set (all of eastern and most of southern Africa). Using nonlexical criteria, Nurse and Philippson (2003) differed somewhat in their view of classification (and history). While acknowledging the northwestern/northern grouping and the western group, they also saw a distinct northeastern group (Uganda, Kenya, and Uganda), but otherwise viewed the remaining languages as a group defined negatively by not sharing the innovations of the west, northwest, north, and northeast.

History

The entire Bantu area historically was covered in work by Vansina (1995), and Vansina (1990) and Ehret (1998) dealt in detail with the northwest/north and east/south/southwest, respectively. An older, slightly outdated, view of the development of Bantu history is found in the work of Oliver (1966) and Phillipson (1977).

Though Ehret and Vansina disagreed on many details, the general outline is clear. Within Niger-Congo, Bantu is part of a grouping currently called Benue-Congo. The ancestors of the Benue-Congo, farmers, lived between what is now the Ivory Coast and western Cameroon, starting some seven millennia ago. By 3000 B.C., the ancestors of the Bantu had emerged and had already divided into what were later to become western and eastern Bantu. During the next millennium, they all moved slowly south and east across Cameroon, carrying the West African planting tradition with them. By 1000 B.C., they had moved much further into the rainforest and had reached various points on or near the Congo (Zaire) River in today's DRC, so that there was a wide range of Bantu communities in the forest (Vansina, 1990: 51–54). There is a popular myth that the huge equatorial rainforest is uninhabitable and uncrossable. In fact, today it has some 12 million inhabitants, spread across 450 ethnic groups (Vansina, 1990: 3), and the early Bantu crossed it easily, following the major rivers (the Congo (Zaire), Kasai, Sankuru, Lualaba, Lomami, and Sangha). By 1000 B.C., the ancestors of today's eastern Bantu were already at the eastern end of the forest, at the western edge of the Great Lakes region, to the east and south of the forest. This is necessarily a shortened and simplified version of events: in particular, it ignores the northwestern and northern Bantu communities, speaking the so-called Forest languages, whose history is somewhat separate and not further followed here.

Ehret saw the ancestors of today's eastern Bantu communities as having divided into two groups, an incipient northern and an incipient southern group, by 3000 years ago, both located in the area west of the West Rift valley in East Africa. The former group likely was to the west and south of Lake Victoria, the latter being west of Lake Tanganyika. The northern group had reached Lake Victoria by the middle of the first millennium B.C. During this period and later, these ancestors came across communities speaking Nilo-Saharan, Cushitic, and Khoisan languages, encounters that contributed to a diversified agriculture and boosted pastoralism. Iron working also had appeared in the region by this time, but its origins are disputed. During the next 500 years, some communities spread around Lake Victoria; some spread across Kenya and northern Tanzania to the coast by the early centuries A.D. and, by a couple of centuries later, others spread south and southeast across Tanzania close to northern Mozambique.

Meanwhile, the southern offshoot of eastern Bantu had left the southern fringes of the rainforest and approached northeast Zambia by the second half of the last millennium B.C. They spread thence into much of Zambia, Malawi, Zimbabwe, southern Mozambique, and eastern South Africa, early Shona societies being established south of the Limpopo River by the third century A.D. These early groups ran across long-established Khoisan peoples in most of the region. Later movements, even into the second millennium A.D., resulted in the current configuration of Bantu communities in South Africa. Western Bantu likewise splintered. Sections moved east and northeast along the upper Congo River and its tributaries, and then southeast, so that nearly all of the rainforest was occupied by western Bantu populations by 1 A.D. Once the ancestors of a southern arm had crossed the lower Congo River and moved out of the rainforest into the adjacent savanna, during the latter half of the last millennium B.C., one section continued south across the Benguela Highlands in Angola and finally into northern Namibia, and another turned east and southeast and moved as far as western Zambia, along the Upper Zambezi River. Most western Bantu populations were in or near their current locations by the late centuries B.C. or the early centuries A.D.

With a few notable exceptions, most major movements of early Bantu-speaking peoples, east and west, were complete by the early centuries A.D., and the ancestors of most current Bantu populations had occupied central, eastern, and southern Africa by that time. Thereafter, some minor movements and local dispersals followed, with much contact, interaction, mixing, and assimilation.

Typology

This section sketches some characteristic features of Bantu phonology, morphology, and syntax, mainly those that occur widely but including a few less widespread, but intrinsically interesting. Exceptions to these generalities occur mainly in northwestern and northern languages.

Phonology

Nearly all Bantu languages have five or seven contrastive vowels, the few exceptions being mainly in Cameroon, Congo, and DRC, with languages with nine or more vowels. Five- and nine-vowel systems derive from earlier seven-vowel systems, the number usually assigned to Proto-Bantu. Despite the apparent similarity of the systems, phonetic realization varies considerably, especially in languages with seven vowels. The full range of vowels is seen in most stem positions, whereas a reduced set occurs in other contexts, such as prefixes and extensions (the derivational suffixes following the stem). Vowel height harmony is widespread, whereby the historical degree-two vowels (the second highest vowels in the seven-vowel system) harmonize and lower to /e/ and /o/ after /e/ and /o/ in the root (and in some languages after /a/) (see Schadeberg, 1994/1995; Hyman, 1999, 2003; Kisseberth and Odden, 2003; Maddieson, 2003).

Proto-Bantu had a few pairs of words differentiated only by vowel length. Some languages have kept these, some have neutralized the length distinction, some have reintroduced it, and others have increased its function, often via loanwords. Phonetic vowel length is typically induced by vowel fusion, following prenasalized consonants, or gliding and 'compensatory lengthening' of the remaining vowel (in sequences of two vowels, /i, e/ and /u, o/ in the first position typically become the glides /y/ and /w/, respectively, before nonidentical vowels).

Most Bantuists credit Proto-Bantu with the following consonant system:

p	t	c	k
b	d	j	g
m	n	ɲ	

Here there is a voiced:voiceless contrast in plosives and a full set of nasals at nearly all the same points of articulation as the plosives. Most contemporary languages have these features, although the voiced plosives have often become continuants. Not shown here, there were also two sets of prenasalized consonants (mb, nd. . .: mp, nt. . .). Most languages still have the voiced set, but the voiceless set has been less stable over time, apparently because of the disparity in voicing between nasal and obstruent.

Some languages still have a simple consonant system that, although altered from the one shown here, derives from it fairly directly. Others have a much-expanded system, partly due to common phonetic processes such as palatalization, gliding, and voicing, but often resulting from a widespread process known as Bantu Spirantization. In this, the two high vowels in the original seven-vowel system affected the preceding plosives, typically producing affricates or fricatives: labial /pf, bv, f, v/ from /p, b/, labials from the nonlabial consonants before the high back vowel, and alveolar or palatal /ts, dz, s, z, etc./ from the nonlabial consonants before the front vowel. Typically, the two high vowels then merged with the degree-two vowels. The result was a smaller five-vowel inventory but a larger consonant inventory with voiced and voiceless plosives and fricatives.

Other consonant processes, geographically more limited, are defined by Dahl's Law and Meinhof's Law. Dahl's Law voices a voiceless stop if the obstruent in the next syllable is also voiceless (so Kikuyu *gek*i from English 'cake'), which has interesting effects in long strings. Possibly linked to this is a more local phenomenon, Katupha's Law, which disallows aspirated consonants in adjacent syllables, deaspirating the first. Meinhof's Law affects sequences of noun, consonant, vowel, noun (consonant), or NCVN(C), deleting the first C, so *ŋgombe* 'cow' would become *ŋombe*. A local variant, the Kwanyama Law, produces the opposite result, *ŋgobe*. Syllables in Bantu are almost universally open, that is, CV or CVV. In restricted contexts, such as prefixes, other shapes (V, N, NCV) occur. A few languages, mostly in the northwest, may have closed syllables (CVC), due to loss of final vowels (but their tones are mostly kept).

Some 95% of Bantu languages are tonal and have a basic contrast between high (H) and low (L), or H and toneless. Contour tones (falling, rising) are usually restricted to bimoraic syllables. Downstepping of each successive H is common. Nouns and verbs show significant differences in the distribution of tone. Nominal prefixes are typically toneless and a number of stem patterns are possible, varying from language to language. Tones in verbs are more complicated than they are in nouns. Verb stems in many languages show a lexical contract between H and toneless, and affixes may also have their own tone, so that in some languages the tone of the verb is more or less the sum of individual tones, modified by certain general processes. In other languages, verb stems have no lexical tone, tone being assigned by general principles, often particular to certain tenses. Even languages with lexical stem tone often have grammatical tone, whereby an H may be assigned to a specific stem mora in certain tenses.

In many Bantu languages, the relationship between an underlying and a surface H is not direct, being modified by widespread principles and processes that favor or disfavor certain configurations. One such is tone spreading (tone of one syllable spreads to the next syllable(s), so being realized on two or more syllables), or tone shift (tone of one syllable is realized only on the next), typically from left to right. Another is avoiding situations whereby phonological structures – typically the intonational phrase or the word – end on an H. A third is the disfavoring of successive (nonsurface) H's, the obligatory contour principle (OCP). Working against the OCP is the plateau principle, whereby a toneless stretch between two H's is avoided. Finally, tones mark certain grammatical functions. Besides being associated with certain tenses or groups of tenses, as already noted, tone often serves, for example, to distinguish statement from question, positive from negative, main from subordinate clause (the latter often including relative clauses), and the third person (H) from the second person singular subject prefix, which are otherwise segmentally identical.

Morphology

Bantu languages have the following word classes: noun, verb, pronoun, adjective (a small class; only a dozen or so are reconstructable for Proto-Bantu), numeral, demonstrative (often a three-way contrast), a small set of quantifiers and interrogatives, preposition (often a compound), and ideophone. One conjunction (*na*) is widespread (see Katamba, 2003; Nurse, 2003; Schadeberg, 2003).

Nouns consist of a stem and a prefix (L). Most prefixes have a CV-shape, stems are of the shapes -CV, -CVCV, -CVCVCV, etc., whereby the last vowel might be part of the stem or it might be a derivational suffix, so in Ha the final vowel of [umwáana] is part of the stem, whereas in *umuhanuuz-i* 'advisor,' *umukén-e* 'pauper,' and *igisus-o* 'example,' the final vowels are derivational suffixes (from *-hanuur-* 'tell', *-ken-* 'miss,' and *-sus-* 'resemble,' respectively). Nouns in many but not all languages have an augment (also called preprefix, initial vowel), consisting of a vowel that reflects the vowel of the prefix. It has various pragmatic and syntactic functions.

All nouns are assigned to a class. Classes have four characteristics: (1) each class has a nominal prefix, (2) there is extensive concord between the noun and the constituents of the noun phrase and the subject and object prefixes in the verb, (3) there are typical singular–plural class pairings, often called genders, and (4) and there is some semantic content to each class and gender. Concord, incidentally, is not always automatic – animacy, for example, can sometimes override automatic class agreement. Typical languages have between 15 and 21 classes and at least six genders, leaving some single classes with no plural pairing. The classes (Cl.) have been given conventional numbers (Cl. 1, 2, 3, 4, etc.) and some genders are widespread (e.g., 1/2, 3/4, 5/6, 7/8, 9/10, 11/10, 12/13, 14/6). Classes 15, 16, and 17 are locative classes and typically have a single member, or even no regular members, their prefixes being added to other nouns. Gender 12/13 (and sometimes 7/8) is a diminutive gender, gender 5/6 (and sometimes 20/21) is an augmentative. Gender 9/10 in many languages appears to act as a dumping ground for nouns that do not fit elsewhere. Nouns may be shifted from one (primary) class to another (derived), typically the classes just

mentioned, in which case the prefix and semantic features of the new class will be added to or replace those of the primary class. Thus there are the Ha words *u-mw-áana* 'child' (Cl. 1), *a-ka-ána* 'small child' (13), *u-tw-ána* 'small children' (13), *i-zí-iko* 'fireplace' (5), and *ku-zí-iko* 'to/on the fire' (16 + 5); also, in Haya (E22), there is *o-mu-ntu* 'person' (1), but *o-lu-ntu* 'tall, slim but slightly ridiculous person' (11). A few northwestern and northern languages have greatly reduced the number of noun classes to a handful, or even to none.

For many decades, it was maintained that with the exception of the derived genders and of gender 1/2 (humans), it was not possible to state the semantic content of most classes and genders, other than by listing typical and obvious groupings, and there were many anomalies. These groupings and anomalies occur across Bantu. Thus gender 3/4 typically contains plants, bushes, trees, and some natural phenomena, but it also widely contains 'year' and 'end,' and, in Swahili, 'mosque'! Contemporary attempts have been made to look at semantic content differently. Rather than trying to reduce content to one or a very few clearly statable characteristics, the new, cognitively inspired approach tries to find coherence in the notion of semantic networks, thus plants > objects made from plants > powerful things (e.g., medicine), or plants/trees > long, extended shape > time trajectory (e.g., 'year, journey'). This still leaves unexplained exceptions, but may lead to even better results when applied to more languages.

It is interesting to note in closing that the final semantic contrasts remaining in languages that have reduced their noun classes almost to zero are those of languages recognized as pidgins. Thus the Cameroonian language Kako (Katanga, 2003: 108), certain D30 languages in the northeastern DRC, and Pidgin Swahili, as spoken in Nairobi, have in common that they have only two or three classes left, retaining only the distinction animate/inanimate or human/nonhuman.

Bantu languages are verby, that is, the verb is not only the organizational center of the sentence but encodes more information than any other word class, information that in, for example, English requires several words. The verb structure is agglutinating and may include up to 20 morphemes in some languages (Nurse and Philippson, 2003c: 9). These two structures cover the main possibilities for the one-word verb:

NEG_1 - prefix - formative - object - root - extension - final vowel - postfinal
prefix - NEG_2 - formative - object - root - extension - final vowel - postfinal

The only two obligatory constituents are root and final vowel, which cooccur in the imperative. Several morphemes may cooccur at prefix, formative, object, extension, and postfinal, typically in a canonical order. The structures differ only in the position of the NEG. Over the past two decades, phonologists have interpreted these linear structures as a hierarchy. Root and extension form the derivational stem: extensions are tonally neutral, have a canonical VC shape, and have a reduced five-vowel system; the derivational stem is the domain of vowel harmony with the root. Derivational stem and final vowel form the inflectional stem, the domain of reduplication, vowel coalescence, and limited consonant harmony with the final root consonant. Derivational stem and object form the macrostem, the domain of certain tonal phenomena. Finally, the macrostem combines with all preceding material to form the verbal word. This synchronic division of the verb into macrostem and prefixes corresponds well with likely historical development – other Niger-Congo languages have the macrostem, to which Bantu prefixes were added later.

Always or nearly always encoded in the inflected verb are subject, tense, aspect, mood, valency, and negation. Subject concord is usually obligatory and encoded at the prefix in both of the preceding structures, whether the subject noun is present or not. Tense is most often encoded at formative, less often at the final vowel or before the prefix. Bantu languages typically have multiple past and future reference: 83% of a database of 100 languages geographically representative of all 500 had between two and five discrete past tenses (40% had two, 32% had three), and 87% had one to three futures (46% had just one, 25% had two). Aspect seems to have been originally marked at the final vowel, but today also appears at formative: perfective, imperfective, progressive, habitual, anterior (also called 'perfect'), and persistive are the commonest aspects. Mood is most often subjunctive, marked by a suffixal [e] at the final vowel. Valency changes are marked at extension and include causative, applicative (encompassing various functions), impositive, neuter/decausative, positional, reciprocal/plurational, repetitive, extensive, tentive, reversive, and passive. Negation appears variously; 51% of the database languages have two negatives, one associated with subordinate clauses, relative clauses, subjunctives, and imperatives, the other with main clauses. The former is typically but not always marked at NEG_2, the latter at NEG_1; 28% of the database languages have a single negative, either at NEG_1 or NEG_2 or pre- or postverbally, and 15% of the languages have more

than two negatives. Tense, aspect, mood (TAM) distinctions in negative verbs may differ from those in positives.

Less often, rarely, or not encoded in the verb are relative markers, focus, pronominal objects, and other categories. Relatives are most often marked before or at prefix in the second structure, and often the main marking is tonal. Focus can highlight several categories (e.g., the lexical verb itself, what follows the verb, or the aspect) and is usually indicated as a second or third morpheme in the formative slot, or verb initially. Pronominal object marking is also variable: some languages allow no object markers in the verb, some allow one, some allow two, and in a few languages four and even five have been recorded, especially in association with an applicativized verb.

A second or third morpheme in the formative slot marks consecutive, itive, or ventive in some languages. Many languages allow compound verbs, whereby the first verb is a tense-marked auxiliary, most often 'be,' and the second, lexical verb carries aspect. Many TAM markers are visibly grammaticalized, reduced forms of auxiliaries.

Syntax

Bantu languages belong to Heine's (1976) Type A, having subject (S) (Aux)-verb (V)-object (O)-X, whereby there may be two objects (double object marking, rather than direct and indirect), and X represents adverbials (the Cameroonian language, Nen, with subject-object-verb (SOV), is the only known exception): prepositions: and noun phrase constituents, including relative clauses and the genitive construction, follow the head noun. The following Ha examples illustrate these and other features mentioned earlier:

inkokó ziníni zóóse záanje
'all my big chickens' (lit. chickens big all my)

izo inkokó ziníni zibíri
'those two big chickens'

igúnira dzuuzúye imbutó
'bag which.is.full.of seeds'

ubwáato bwa-dáatá
'canoe of-father'

ba-ø-teera ibiharagi
'they-sow beans' (postverbal focus)

ba-ø-ra-téera
'they sow' (verbal focus)

wari wágiiye heéhe
'where had you gone?' (lit. you.were you.went where)

keéra ha-rabáaye
'once there-was' (Class 16)

yasutse-mwó amáazi
'she.poured-in water' (Class 16)

urondera-kó (Class 17)
'. . .where you sought' (lit. you sought-where)

yamúhaaye umukáaté umwáana kumwóonga
'she.gave bread to.child at.river'

The first four examples illustrate the order of constituents of the noun phrase. Harjula (2004: 131), from whom these examples come, stated that some of the constituents may change their order "without a change in the meaning" (in other languages, a change of place implies a change in emphasis) and that demonstratives precede the noun (in other languages, they may precede or follow). The fifth and sixth examples show one kind of focus contrast and one way of doing it: the form showing the close relationship between verb and postverbal constituent, also called the conjunctive, has a zero marker (ϕ) between subject marker and verb, whereas the form with focus on the verb, the disjunct, has a morpheme *ra* and retains the H of the stem. The seventh example shows a typical compound verb ('be' followed by main verb) and a wh-question: the wh-word typically retains the position of the element replaced, at least for nonsubjects. Yes/no questions are indicated either by a question marker at the beginning or end of the sentence, or by use of tone. Examples 8–10 show locatives in subject, object, and relative function, respectively, spatial relations being typically coded on the verb. The last example shows the ditransitive verb 'give' with two objects and an adverbial. Of this, Harjula said: "When there are two object prefixes the more indirect (i.e., the patient) is closer to the stem." This runs counter to Bearth's (2003: 127) claim that "the widespread tendency in Bantu languages is to assign the positions next to the verb on account of a hierarchy of parameters defined, in terms of (i) animacy of the referent (human > animate > inanimate), (ii) semantic role relationship (beneficiary > goal > patient > locative), (iii) participant category (first- > second > third person), and (iv) number (plural > singular)". This is true of noun phrases following the verb, and their mirror image, object prefixes preceding it. Finally, although the canonical word order is SVO, considerable word-order variation is possible for pragmatic purposes. The position to the right of the verb, in particular, acts as a focus position.

Barbados: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of Barbados is English, with 268 000 speakers in total. The second language of Barbados is Bajan, also known as Barbadian Creole English, with 259 000 speakers existing in a continuum with 13 000 standard English speakers. The English of Barbados is considerably less creolized than other Englishes in the region and it is reported that even the basilect is closer to standard English than those of Jamaica or Guyana. This has led to some claiming that Bajan may not be a creole. Be that as it may, the decreolization of Bajan has been enhanced by early repressive laws (especially The Sunday and Marriage Act of 1826), the relatively small size of the island and its rather flat topography; linguistic communities could not remain isolated from the standardizing forces for long. Now, it is reported to be increasingly influenced by American English and exists in a Creole continuum with other Englishes spoken in the region. In Barbados, the habitual use of Bajan is perceived as indicative of low social and educational status. Literacy is 97.4%, defined as people of 15 or over who have attended school.

The dominant role of English in Barbados is rooted in the fact that Barbados was never colonized by the

Spanish and was uninhabited when claimed by the British in 1624. The first colonists, growing tobacco, were mainly slaves as well as British farm owners and administrators. During the English Civil War, prisoners of war, Irish rebels, and petty criminals were deported there, ensuring that Barbados English corresponded to the English of the British poor. When production switched to the more labor- and capital-intensive production of sugar in the 1640s, African slaves were brought to the island, further adding to linguistic complexity.

Barbados also played an important role in the spread of English. The effect of the expansion of the sugar plantations was to force smallholders off the land and to disperse to other islands. Emigration from Barbados played an important role in the development of English creoles in, among others, Trinidad and Tobago and Panama. This was enhanced by the fact that Barbados was an important staging post in the Caribbean slave trade. After emancipation in the 19th century Barbados developed a surplus of laborers, who traveled as indentured laborers throughout the Caribbean, taking their English with them.

Bar-Hillel, Yehoshua (1915–1975)

J Léon, Centre National de la Recherche Scientifique, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Yehoshua Bar-Hillel (see **Figure 1**) was a mathematician, logician, and philosopher of science. He is very famous for his contributions to pioneering fields ranging from syntax (categorial grammar) and theory of information to evaluation of early machine translation and information retrieval. He republished his main papers in two collections, *Information and language* in 1964, containing his works on machine translation, syntax, information retrieval, and information theory, and *Aspects of language* in 1970, dedicated to Rudolf Carnap and containing his works on philosophy of language (indexicality, context-dependence, and pragmatic implication). In addition, he edited several colloquium proceedings on logic, pragmatics, set theory, and philosophy of sciences, which he organized in Jerusalem from 1965 until 1971.

Figure 1 Yehoshua Bar-Hillel.

Yehoshua Bar-Hillel was born in 1915 in Vienna and went to Palestine in 1933. He carried out his studies at the Hebrew University of Jerusalem with an interruption of one year (1934) to join a kibbutz. He took his M.A. in philosophy and mathematics in 1938. Influenced by the reading of Carnap's *Logische Syntax der Sprache*, he began a Ph.D. while teaching mathematics in high schools. From 1942 to 1945 he fought in the Jewish Brigade Group of the British Army and had just enough time to submit his Ph.D. in 1947, on a theory of syntactic categories under the supervision of S. H. Bergmann (Bar-Hillel, 1950), before the beginning of the Israeli war of independence, in which he fought and lost one eye. In 1949 he began an academic career at the Hebrew University of Jerusalem as Research Fellow before going to the United States, where he spent four years. In 1950 he

obtained a fellowship from the Hebrew University at the philosophy department of the University of Chicago, where he met Rudolf Carnap. In 1951 he was appointed to the MIT Research Laboratory for Electronics as a research scholar for the study of the application of computers to linguistic work, most notably machine translation (MT). He had been dubbed the first academic to work full-time in the field of MT. When he returned to Israel in 1953, he was appointed Senior Lecturer in Philosophy (1953–1958), then Associate Professor of Philosophy (l958–196l), and finally Professor of Logic and Philosophy of Science (196l–1975). He died prematurely, before his 60th birthday, after a long illness.

Bar-Hillel contributed substantially to MT by his critical approach and his pioneering proposals on the automatization of syntactic analysis through categorial grammar. Acquainted with international auxiliary languages, he was interested by the possible effect of MT on international communication, especially among scientists. He organized the first conference on MT in 1952 and dedicated many papers to it in the 1950s and 1960s. In 1958 he obtained a research contract through the National Science Foundation to study linguistic data processing, including a critical investigation on the state of machine translation. He published the results in a critical report that described the inadequacy of the theoretical basis of MT (Bar-Hillel, 1960). He especially argued against the feasibility of full automatic high quality translation (coining himself the acronym FAHQT) and advocated post-editing and machine-aided translation. His main argument is well-known: he demonstrated the need for extralinguistic knowledge, inferences, and coreferences (indexical expressions) in order to translate ambiguous words like 'pen' in a sentence like "the box was in the pen" (Léon, 2004). This crucial issue for automatic understanding was addressed by artificial intelligence only several years later. His critical report instigated the creation of the ALPAC committee in 1964, the report of which (known also as the Pierce report), published in 1966, led to the suppression of funds for MT research, hence the disparition of MT centers and researchers all the world over.

Through the prism of MT criticism, Bar-Hillel tackled several issues in the area of philosophy of language, such as indexicality (1954a) and idioms (1955). He was also concerned with set theory and semantic information. Thus, inspired by Shannon's mathematical theory of communication, he tried, in collaboration with Carnap, to define how to measure the meaning of information (Carnap and Bar-Hillel, 1952).

Bar-Hillel's main contribution to MT was his idea of operational syntax, unprecedented among MT researchers, in order to mechanize syntactic analysis. He gave the outline of a quasi-arithmetical description of syntactic structure, a categorial grammar, combining Ajdukiewicz's logics and Harris's method in order to test the syntactic connexity of strings. Sharing Carnap's and Tarski's views, Bar-Hillel advocated a logicist conception of syntax. This was precisely the conception that was criticized by Chomsky and gave rise to the well-known controversy between the two scientists – who were also very good friends – about the role of logic and formal semantics in linguistics in the journal *Language* (Bar-Hillel, 1954b; Chomsky, 1955). Later, Bar-Hillel adopted some of Chomsky's views. While in a first version of his operational syntax (1953) he stood by Harris's immediate constituency, he later rallied to Chomsky's transformational grammar to account for discontinuities and complex sentences (Bar-Hillel, 1960: Appendix II). In the following years, he investigated the complexity of categorial grammar with his associates, Chaim Gaifman, Asa Kasher, and Shamir Eliyahu, of the Applied Logic Branch of the Hebrew University (Bar-Hillel *et al.*, 1967). They opened up a new field that later gained more and more importance in formal and computational linguistics (see, for example, Oehrle *et al.*, 1988).

Barthelémy, Jean-Jacques (1716–1795)

Y Gruntfest, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

A prominent French explorer of Classical and Oriental antiquities, the abbé Jean-Jacques Barthélemy was born in Cassis in southern France and educated in Marseilles by Jesuits and Lazarists, acquiring a good knowledge of Classical and Oriental languages, including Hebrew, Syriac Aramaic, and Arabic.

In 1744 Barthélemy went to Paris and began his lifelong scholarly activities in the Royal Cabinet of Medals and, from 1747, in the Academy of Inscriptions. The sphere of Barthélemy's scholarly interests included numismatics, sphragistics (the study of seals and signets), paleography, epigraphy, and languages.

Barthélemy's main achievements in linguistics were connected with his exploration of Oriental epigraphic monuments. From 1754 to 1764 Barthélemy, coincidentally with the English scholar Swinton, but quite independently and more successfully, deciphered the Palmirene and Phoenician scripts. He thereby became the founder of Semitic epigraphy and the scientific investigation of the Phoenician language. He also laid the foundations for the comparative study of Afro-Asiatic languages, having demonstrated, with a few but convincing examples, the affinity between Coptic (which he thought to be identical with Ancient Egyptian) and Semitic languages. However, his erudition and sagacity sometimes betrayed him. Accordingly, he uncritically accepted the bizarre idea of de Guignes that the Chinese people were descendants of Phoenician colonists and that the Chinese hieroglyphs included Phoenician letters.

Barthélemy's greatest work, *Voyage du jeune Anacharsis en Grèce*, a multivolume popular description of the morals and manners of ancient Greece, was published in 1788. This book – the fruit of 30 years' work – was a great success. It was reissued many times in French and was translated into seven languages. The year following its publication Barthélemy was elected a member of the French Academy.

The Revolution caused dramatic upheavals in Barthélemy's life. He lost his positions, and his material condition was reduced to a minimum. In 1790 he was arrested. But his fame was so great that after 16 hours of confinement' he was released and allowed to resume his scholarly work. However, his health was deteriorating and at the age of 79 he passed away – a true classicist! – with a volume of Horace in his hands.

Barbados: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of Barbados is English, with 268 000 speakers in total. The second language of Barbados is Bajan, also known as Barbadian Creole English, with 259 000 speakers existing in a continuum with 13 000 standard English speakers. The English of Barbados is considerably less creolized than other Englishes in the region and it is reported that even the basilect is closer to standard English than those of Jamaica or Guyana. This has led to some claiming that Bajan may not be a creole. Be that as it may, the decreolization of Bajan has been enhanced by early repressive laws (especially The Sunday and Marriage Act of 1826), the relatively small size of the island and its rather flat topography; linguistic communities could not remain isolated from the standardizing forces for long. Now, it is reported to be increasingly influenced by American English and exists in a Creole continuum with other Englishes spoken in the region. In Barbados, the habitual use of Bajan is perceived as indicative of low social and educational status. Literacy is 97.4%, defined as people of 15 or over who have attended school.

The dominant role of English in Barbados is rooted in the fact that Barbados was never colonized by the

Spanish and was uninhabited when claimed by the British in 1624. The first colonists, growing tobacco, were mainly slaves as well as British farm owners and administrators. During the English Civil War, prisoners of war, Irish rebels, and petty criminals were deported there, ensuring that Barbados English corresponded to the English of the British poor. When production switched to the more labor- and capital-intensive production of sugar in the 1640s, African slaves were brought to the island, further adding to linguistic complexity.

Barbados also played an important role in the spread of English. The effect of the expansion of the sugar plantations was to force smallholders off the land and to disperse to other islands. Emigration from Barbados played an important role in the development of English creoles in, among others, Trinidad and Tobago and Panama. This was enhanced by the fact that Barbados was an important staging post in the Caribbean slave trade. After emancipation in the 19th century Barbados developed a surplus of laborers, who traveled as indentured laborers throughout the Caribbean, taking their English with them.

Bar-Hillel, Yehoshua (1915–1975)

J Léon, Centre National de la Recherche Scientifique, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Yehoshua Bar-Hillel (see **Figure 1**) was a mathematician, logician, and philosopher of science. He is very famous for his contributions to pioneering fields ranging from syntax (categorial grammar) and theory of information to evaluation of early machine translation and information retrieval. He republished his main papers in two collections, *Information and language* in 1964, containing his works on machine translation, syntax, information retrieval, and information theory, and *Aspects of language* in 1970, dedicated to Rudolf Carnap and containing his works on philosophy of language (indexicality, context-dependence, and pragmatic implication). In addition, he edited several colloquium proceedings on logic, pragmatics, set theory, and philosophy of sciences, which he organized in Jerusalem from 1965 until 1971.

Figure 1 Yehoshua Bar-Hillel.

Yehoshua Bar-Hillel was born in 1915 in Vienna and went to Palestine in 1933. He carried out his studies at the Hebrew University of Jerusalem with an interruption of one year (1934) to join a kibbutz. He took his M.A. in philosophy and mathematics in 1938. Influenced by the reading of Carnap's *Logische Syntax der Sprache*, he began a Ph.D. while teaching mathematics in high schools. From 1942 to 1945 he fought in the Jewish Brigade Group of the British Army and had just enough time to submit his Ph.D. in 1947, on a theory of syntactic categories under the supervision of S. H. Bergmann (Bar-Hillel, 1950), before the beginning of the Israeli war of independence, in which he fought and lost one eye. In 1949 he began an academic career at the Hebrew University of Jerusalem as Research Fellow before going to the United States, where he spent four years. In 1950 he

Barthes, Roland (1915–1980)

M Toolan, University of Birmingham, Birmingham, England, UK

© 2006 Elsevier Ltd. All rights reserved.

Roland Barthes, a French critic and theorist of literature and culture, was very much associated with the Parisian intellectual ferment and contention of the 1960s and beyond (especially at the École pratique des Hautes Études, and in his final years as the chair of literary semiology at the Collège de France). Barthes came to international prominence for his structuralist-informed but primarily semiological analyses of myths and cultural practices (see his *Mythologies*: Barthes, 1957).

For stylistics and linguistic criticism, Barthes is chiefly influential in three texts: his early essay on the structural analysis of narrative, in which his ideas of functions, indices, and catalyzers were introduced; *Mythologies*, his collection of essays which innovatively applied structuralist-anthropological methods to an interrogation of the overlooked systematicities of popular culture and mass media (from wrestling to restaurant menus to the Eiffel Tower); and his 1970 study *S/Z*, on the systematic reversals and deceptions in a Balzac story, in which a procedure of detailed commentary on blocks of the story's text (lexias) in terms of five shaping semiotic codes (the hermeneutic, proairetic, semic, cultural, and symbolic) was elaborated in a virtuoso analysis. By analyzing phase-by-phase Balzac's short story 'Sarrasine,' he dealt with the experience of reading, the relations of the reader as subject to the movement of language in texts. According to Barthes, classic criticism has never paid proper attention to the reader, even though the reader is the space where all a text's aspects meet, and a text's unity lies not in its origin but in its destination: "The birth of the reader must be at the cost of the death of the Author."

His cultural criticism combined subtle philosophical critique with personal, and even confessional, individuality of response (and in some respects created and prepared audiences for the different bodies of work of Derrida and Lacan). He recast characters and readers as shimmering confluences of traces, signs, and absences, rather than abbreviated notations of fixed and stable free-standing individuals (the latter view became for him part of an insupportable rationalist, liberal, and bourgeois reading of culture). He sought to elaborate a logic of writing and reading which was based on pleasure (*jouissance*), a concept whose erotic aspects he did not hesitate to acknowledge and explore. Indeed, in his final years Barthes came to assert that the 'system' of a language – by contrast with the anti- or suprasocial pleasures of literature, music, and photography – is repressive, constraining, even a kind of violence, which we must resist. In such ways, Barthes contributed to the poststructuralist and deconstructionist turn. *Camera Lucida,* the last book Barthes published, was in part a grieving over his recently deceased mother; but it also introduced a final pair of antithetical concepts: the *studium*, or scientific-analytic approach, and the *punctum* (of a poem, photograph, etc.): that point or small detail that catches the eye or snags in memory, something poignant or unexpected but somehow prepared for. In all his work – like Beckett – he championed the heterodox and the avant-garde, committed to maintaining a critical discourse that would not be assimilated or appropriated into the dominant culture, the discourse of power and the powerful.

Barthes, Roland: Theory of the Sign

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The sign theory of Roland Barthes (1915–1980) is distributed across a large number of works in literary theory and communications, from his early analysis of '*ecriture blanche*' in the work of Albert Camus, to the pinnacle of his poststructuralist achievements in books such as *S/Z* (1970), *Le plaisir du texte* (1973), and *La chambre claire* (1980). Barthes' sign theory is explicit in theoretical essays from the 1960s such as his analysis of an advertisement – and, by association, much advertising imagery – in 'The rhetoric of the image' (1977a) and implicit in essays such as 'The death of the author' (1977b) that function more like manifestoes than sign analyses. However, it is probably his small 1964 book, *Elements of semiology* (English trans., 1967a), that contains Barthes' most focused comments on sign theory.

While Barthes continued to write about literary criticism, early work such as *Le degré zero de lécriture* (1953) was also carried out alongside such explicitly analytic disquisitions as the essay on signs, 'Myth today,' in *Mythologies* (1957; English trans., 1973). This acted as the conclusion of a series of brief articles written for French magazines in the period 1954 to 1956 that Barthes had drawn together for publication. Each dealing with a 'mythology' – wrestling, the haircuts of the Roman characters in Mankiewicz's film of *Julius Caesar*, the face of Garbo, *steack frites*, striptease, the New Citroën, and the brain of Einstein – the essays were evidence for Barthes that "myth is a language" (1973: 11). More importantly, though, Barthes claims to have actually initiated semiology in this work (1973: 9), instituting the general science of signs that Saussure had first called for (in print) 41 years before.

As a type of speech (as Barthes insisted it was) the myth that creates mythologies produces two levels of signification. The first level of this system Barthes calls the 'language-object': "it is the language which myth gets hold of in order to build its own system" (1973: 115). This level is the domain of the signifier (sound pattern) and signified (mental concept) that Saussure envisaged as being connected in the brain to produce a (linguistic) sign. For Barthes, this level is where straightforward indicating takes place: denotation. The second level, on the other hand, is 'metalanguage': a language that speaks about the first level. The level of metalanguage is constituted by connotation and Barthes suggests that it is 'cynical' because it relies on the level of denotation to naturalize any ideological proposition that it embodies.

In terms of the analysis of the sign, *Mythologies* is a crucial forerunner to the systematic disquisition in *Elements of semiology* seven years later. The visual nature of many of the mythologies in the former book are taken for granted as Barthes applies what was originally a linguistic conception of the sign (Saussure's). In the period leading up to *Elements of semiology*, Barthes also continued to work on sartorial signification of vestments. *Système de la mode* (1967b) is concerned with the nature of the sign of women's vestments as illustrated in fashion magazines. Barthes had been working on the analyses presented in this book during the period 1957–1963, and his ruminations carry over into *Elements of semiology*. These examples are clear evidence that, from a very early stage, Barthes was interested in putting forth a general notion of the sign that, for all its reliance on a thoroughly linguistic basis, he saw as perfectly adequate for understanding verbal and nonverbal semiotic systems alike.

In *Elements of semiology*, Barthes wants to go well beyond the concept of 'sign' that is evident in the teaching of some linguists. In general, he seeks to explicate an understanding of language not as a collection of discrete signs but as an organizing principle of discursive fields. Such discursive fields would not be constituted by verbal signs (and their connections) alone. They would instead take the lead of language as a system of organization. Indeed, he suggests somewhat giddily that "linguistics is not a part of the general science of signs, even a privileged part, it is semiology which is a part of linguistics: to be precise, it is that part covering the *great signifying unities* of discourse" (1967a: 11). Despite Barthes' impetus to embrace the semiotics of verbal and nonverbal systems, then, his sign theory is nevertheless geared to a notion of language as the touchstone of organization.

For Barthes, it is the repetition of signs in successive discourses that entails that each sign becomes an element of the language (*la langue* – "language without speech") (1967a: 14–15). However, according to Saussure, *langue* is a heuristic means for thinking about the language system; language without speech would actually be impossible. Barthes therefore draws attention to the fashion system, where signs work in a somewhat different way. For Barthes, the garment cannot be an instance of speech; it is instead always "a systematized set of signs and rules: it is a language in a pure state" (1967a: 26). This is because "fashion clothes (as written about) are the language at

the level of vestimentary communication and speech at the level of verbal communication" (1967a: 26). The feature of the sign that seems to be most crucial for Barthes and that encourages him to make the counterpoint to Saussure is the idea of the sign as part of an 'ideological' organizing principle. Whereas individual or collective uses of speech (or individual or collective usages of food, the analogous example he uses) (1967a: 28) might become part of language (or alimentary language) as a result of repetition or 'evolution,' what makes up the constituents of 'language' in the case of fashion is the highly directed work of a 'deciding group.'

If it was not clear from the analysis of 'myth' offered by Barthes in *Mythologies*, then *Elements of semiology* makes it apparent that central to his theory of the sign is the way that it can be not simply an ideological 'vehicle' but, in fact, ideological through and through. This is apparent in his comments on the nature of the *signifiant* and the *signifie* (usually translated into English, potentially confusingly, as 'signifier' and 'signified'). Nevertheless, Barthes' formulations in this area are the subject of some questions regarding their consistency and their Saussurean credentials. One reason for this is suggested by Roy Harris – that Barthes came to Saussure relatively late and that his understanding of the Saussurean sign was already refracted through the lens of his reading of Lévi-Strauss, Lacan, Jakobson, Martinet, Benveniste, and especially Hjelmslev (2003: 136). Certainly, the latter is influential in Barthes' theory of the sign, beyond even the conceptions of denotation and connotation. Barthes, for example, introduces accurate definitions of the *signifiant* and *signifie*, but he immediately reframes their operation in terms of 'form,' 'substance,' 'plane of expression,' and 'plane of content' (cf. Hjelmslev, 1970).

Barthes is initially very clear about the *signifiant* and *signifie*: they are an acoustic image and a mental concept, respectively. He underlines the latter, in fact, by writing "the signified [*signifie*] is not a thing but a mental representation of the thing" (1967a: 42). However, Harris points out that while Barthes' formulations about the internal relations in the sign are unexceptional, his definition of what the sign (*signe*) is, concentrating on the relation between *signifiant* and *signifie*, misses its mark. For Harris, Barthes:

> fails to see that for Saussure the *signe* is indeed not only a linguistic unit but *the* linguistic unit, and not a mere 'rapport' between its constituent parts. *A fortiori*, the fundamental Saussurean tenet that in *la langue* semiological relations take priority over – and determine – units sinks without trace in Barthes' exposition … Barthes had not only missed the most original theoretical feature of Saussure's account of linguistic structure, but reinstated precisely the concept that Saussure was at pains to reject, i.e. the sign as a mere correlation between antecedently given items (formal and semantic) (2003: 141).

Yet Barthes' placing of the sign before the semiological relations of *la langue* has a further twist that has been undoubtedly influential and has served to distort the picture for those who take the account in *Elements of semiology* to be the definitive exposition of Saussure. In drawing attention to the "nature of the signifier [*signifiant*]", Barthes writes that:

> it is purely a *relatum*, whose definition cannot be separated from that of the signified [*signifie*]. The only difference is that the signifier is a mediator: some matter is necessary to it. But on the one hand it is not sufficient to it, and on the other, in semiology, the signifier can, too, be relayed by a certain matter: that of the word. This materiality of the signifier makes it once more necessary to distinguish clearly *matter* from *substance*: a substance can be immaterial (in the case of the substance of the content); therefore, all one can say is that the substance of the signifier is always material (sounds, objects, images) (1967a: 47).

It is fairly clear why Barthes makes this un-Saussurean assertion about the *signifiant*, and indeed, he is not shy about it:

> In semiology, where we shall have to deal with mixed systems in which different kinds of matter are involved (sound and image, object and writing, etc.), it may be appropriate to collect together all the signs, *inasmuch as they are borne by one and the same matter*, under the concept of the *typical sign*: the verbal sign, the graphic sign, the iconic sign, the gestural sign are all typical signs (1967a: 47).

For Barthes, the business of establishing a semiology in which verbal and nonverbal signs can be considered equally leads him to override the fundamental principle of Saussure in which the relations within the linguistic sign are purely mental. This is probably the most characteristic feature of Barthes' theory of the sign, although unfortunately, the fact that *Elements of semiology* has often been treated as a faithful explication of Saussure rather than as a manifesto has prompted the erroneous belief that Saussure's *signifiant* is the same as Barthes' (see, for example, Bignell, 1997; Cobley, 1996).

Another feature of Barthes' revision of Saussure concerns the vaunted 'arbitrariness' of relations in the sign, and here Barthes takes his cue from Benveniste and then Martinet. With respect to the word *ox*, Barthes suggests, after Benveniste, that the relation of *signifiant* and *signifie* "is by no means arbitrary (for no French person is free to modify it), indeed, it is, on the contrary, necessary" (1967a: 50). Ultimately,

however, Barthes suggests that the relation is one that is determined by different degrees of 'motivation.' An unmotivated system, he argues, is one where signs are not founded by convention but by unilateral decision; so for him, signs in *la langue* are not unmotivated, but signs in the world of *fashion* (where there is an elite organizing body) are. Signs are motivated, on the other hand, when the relation between *signifiant* and *signifie* is analogical (1967a: 51). This is, once more, evidence of Barthes' attempt to smooth the transition from Saussure's linguistic sign to a general semiology containing, for example, pictorial signs whose *signifiant/signifie* relation is, frequently and unavoidably, one of motivation.

It is evidently important for Barthes that there is an analytic unity in his theory of both verbal and nonverbal signs, chiefly because the ravages of ideology, when exposed, would be less convincing if they were distributed unevenly across different kinds of signifying systems. Indeed, Barthes' justly famous essays on photography are important in this respect because they indicate that the denotative sign enacts a motivated relationship often as if it were in the service of 'validating' the injustice of the connotative sign, establishing its literalness and helping to 'ground' ideology. In identifying and analyzing Barthes' theory of the sign as distinct from Saussure's, then, it is crucial to recognize these imperatives.

Mattio Giulio Bartoli, one of the founders of the so-called 'Neolinguistic school,' was born September 22, 1873 in Albona d' Istria (now Labin in Croatia), then a small Italian-speaking town in the Istrian province of the Austro-Hungarian empire. Having grown up in the diaspora, he became a fervent Italian nationalist, using linguistic and ethnological arguments to defend the 'Italian character' of his native Istria.

Bartoli studied classical and romance philology in Vienna, Strasbourg, and Paris. Among his masters were the heads of two linguistic schools in conflict, two outstanding scholars, Wilhelm Meyer-Lübke (*see* **Meyer-Lübke, Wilhelm (1861–1936)**) the doyen of the second generation of the Neogrammarians, and Jules Gilliéron (*see* **Gilliéron, Jules (1854–1926)**), one of the founders of linguistic geography.

In 1907, Bartoli became professor of Classical and Romance Philology at the University of Turin; for a time he also taught general linguistics and German language and literature. One of his best students was Antonio Gramsci, the founder of the Italian Communist Party. Starting in the early 1920s, Bartoli dedicated a good deal of his time to the Italian linguistic atlas (*Atlante Linguistico Italiano*), which was continued by G. Vidossi, B. Terracini, and C. Grassi (vol. 4 published in 1997) after Bartoli's death in 1946. From 1926 onward, Bartoli also directed the romance philology section of the *Archivio glottolegico italiano,* one of the most prestigious philological

however, Barthes suggests that the relation is one that is determined by different degrees of 'motivation.' An unmotivated system, he argues, is one where signs are not founded by convention but by unilateral decision; so for him, signs in *la langue* are not unmotivated, but signs in the world of *fashion* (where there is an elite organizing body) are.
